Subscription Rates

Subscription one year $3.00
Postage prepaid in United States and possessions, Mexico, Cuba and Panama.

Subscriptions for foreign countries one year, postage prepaid 4.50
Subscriptions for Canada, one year, postage prepaid 3.75

The Scientific American Publications

Scientific American established 1845 ..... per year $3.00
Scientific American Supplement (established 1876) 5.00
American Homes and Gardens 5.00
The combined subscription rates and rates to foreign countries including Canada will be furnished upon application.
Remit by postal or express money order, bank draft or check

Munn & Co., Inc., 361 Broadway, New York

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are worth the article alone and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately and in simple terms, the world's progress in scientific knowledge and industrial achievement. It seeks to present this information in a form so readable and readily understood, as to set forth and emphasize the inherent charm and fascination of science.

The Utility of Beauty

EVIDENCES are not wanting of a growing appreciation of the fact that in those broad fields of human activity which are covered by the architect and the engineer, there is no necessary antagonism between the useful and the beautiful. Too long the idea has prevailed that whenever we depart from those forms and dimensions which are demanded by a strict consideration of prospective returns on the money invested, a more or less serious money loss will be involved. Now, although there may be some truth in this conviction, it is not altogether true. For the public taste has been educated to a point where it is beginning to be recognized that in the construction of municipal works and of the more monumental of our commercial buildings, their value is distinctly increased, even as to their revenue-earning capacity, in proportion as they are invested with true beauty and dignity.

Even at this early day in the movement toward the realization of the city beautiful, there are several notable instances of the recognition of the principle above referred to, and we draw attention to the fact that when the architects of the office building which forms the subject of our front-page engraving urged upon the syndicate who are financing the structure the advisability of setting the front walls of the building well back from the columns of the loggia near the top of the building and also proposed to run up the pyramidal roof in solid granite, free from windows, the committee in spite of the fact that much very valuable rentable floor space would be lost, were willing to make the sacrifice for the sake of the gain in architectural effect. The concession was made on the understanding and recognition of the fact that the modern building which possesses architectural beauty and dignity is preferred by prospective tenants to those bald and cheerless monstrosities whose architects seem to have taken a perforated packing case as their model.

Other and even more notable instances are the two magnificent terminal buildings of the Pennsylvania and the New York Central railroad companies. The early plans for the station building of the New York Central showed a 25-story office building, towering above the station proper. Nevertheless, upon further consideration, the company decided to forego the large financial profits which could have been secured from a building of this character, in favor of the more beautiful and dignified structure which will form the easterly entrance gate to their great railroad system.

So also, the Pennsylvania Railroad, in the same admirable spirit of regard for the architectural embellishment of New York city, chose to erect over their terminal a monumental classic structure barely exceeding it in height of façade, which is one of the most handsome buildings of its kind in the world. Here also had the company chosen to do so, they could have erected a princely revenue by erecting a towering building upon the site, 100 by 700 feet square, occupied by this station.

Mention should also be made of that exquisite architectural structure which forms the home of the New York *Herald*. Too hasty considerations of utility might have prompted the erection on this valuable site of a typical skyscraper; but we venture to believe that the appreciation of the motives which led to the construction of this modest but beautiful building must have gone far to offset any pecuniary loss due to its limited size.

A New Danger for the Airman

THE two terrible accidents which occurred the opening day of the great circuit aeroplane race from Paris to London and return have opened the eyes of the aviation world to an ever-threatening danger to those who navigate the air in present-day aeroplanes. The monoplanes of two competitors caught fire in the air and fell like flaming meteors to the ground. The unfortunate airmen, strapped in behind their burning gasoline tanks, were frightfully burned before they were killed by the fall.

These catastrophes have brought out afresh, and very forcibly, the constant danger from fire in the flimsy structure of sticks and cloth that constitutes the modern aeroplane. In the first case of a machine catching fire in flight, which happened in Germany more than a year ago, we pointed out the necessity of fire-proofing the burnable parts of these machines, or of making them entirely of metal, so that they would not be consumed in case of fire. The late John B. Moisant claimed to have designed and built, in France, the first all-metal monoplane nearly two years ago, and of late a number of machines have been built there and in America largely of metal construction; but the great majority of aeroplanes in actual use are constructed of wood and cloth. Only a few days before the double disaster in France, above mentioned, a new biplane caught fire at Mineola while in flight, the whole center section being burned out before the machine came to earth and the flames were extinguished. There are several ways in which an aeroplane can catch fire from the gasoline motor that propels it. If the carburetor is located near and over the exhaust and a slight leak occurs, the dripping gasoline can easily ignite and set fire to the carburetor, thus creating a sufficient flare-up to ignite the cloth and woodwork. Hamilton's machine was partially burned in this way during preparations for a flight in the West. In a monoplane such as the Blériot, where the sides of the body at the front are formed of sheet aluminium, and where an inclined partition separates the aviator from the motor, there is a chance that the machine itself will not catch fire immediately and that the aviator may be able to shut off the gasoline and let that in the carburetor burn itself out. As the gasoline tank is placed back of the inclined partition, there is a fair chance that the flame will not reach it, but, on the other hand, the aviator may not be aware of the fire until the machine bursts in flames and it is too late to avert disaster. Such was evidently the case with Landron, in the De Pishoff monoplane.

There is another way in which the carburetor can ignite, and in all probability the accident happened in this way in Landron's case. A weak mixture or an air leak in the inlet pipe will sometimes cause a back-fire through this pipe to the carburetor, and there is an even chance that the gasoline in the carburetor will thus become ignited. Since the carburetor was hidden away beneath the engine hood, the aviator was probably unaware of the fire until the flames came back in his face. The aeroplane was flying at the height of nearly 2,000 feet when it caught fire. From the huge sheet of flame that shot forth, there is little doubt but that the gasoline tank ignited soon after the carburetor.

From the foregoing it would seem that in a monoplane the gasoline tank should be carried in the body, back of the aviator, the fuel being forced to the carburetor under pressure. This arrangement would be similar to that used on some automobiles, where the tank is at the rear end of the car. There should also be a shut-off that can be quickly turned by the aviator in case of emergency. In a biplane, instead of being placed above the lower plane just back of the aviator, the tank should be located beneath this plane, or should be suspended between the outriggers well to the rear. There have been several instances in which a machine, when it plunged to the ground, has caught fire owing to the proximity of the gasoline tank to the motor and the fact that the engine was still running. In the smashing of the R. & E. P. monoplane, when it upset in making a turn in a wind of some 40 miles an hour, the body of the passenger, Lieut. Depuit, was charred beyond recognition owing to the debris catching fire instantly when the machine struck the ground.

It will be seen, from the various accidents here mentioned, that the danger of fire is an ever present one, and one that every precaution should be taken to abolish. Because of the wide experience had with the internal-combustion motor in automobiles, the action of a gasoline motor, and the accidents to which it is liable, are so well known as to render the loss of a single life from fire in the air quite inexcusable. Designers of aeroplanes should see to it in the future that there is no possible chance of their machines igniting while in flight.

Biology and Biography

PROBABLY no phenomenon within the range of natural science appeals to us with greater interest than that complex series of events and actions which we call life. For we ourselves are living beings, and those effects which we observe in other creatures in the dispassionate spirit of scientific inquiry, are known to us by direct experience also, and touch the innermost nature of our conscious being. Ordinarily, when we speak of human life, we mean that succession of mental experiences with which the biographer and the novelist are concerned —the "mind life" which begins anew with each individual—rather than the biological or "material life"—which is absolutely continuous from generation to generation. The "mind life" may seem to us so to transcend the mere biological phenomena accompanying it, that these in comparison appear insignificant. Yet it is well to remember that the two stand in the closest possible relation. It appears that there can be material life without consciousness, but so far as we know, there is no consciousness without material life. Unconscious states in life we know from our own normal experience of sleep, as well as from abnormal diseased conditions ranging from a passing swoon to a mortal coma. We know, too, that by reflex action we can perform, wholly or in part aside from conscious control, various motions of a useful character. It is possible that in low forms of organisms all actions are of this kind; there seems to be no warrant, for example, for supposing that the amœba is in any sense "conscious."

As has already been indicated, however, such consciousness as we know is not only invariably associated with material life, but its character, its "color," is inextricably bound up with the past and present conditions and physical experiences of the individual. Now these conditions may be said to depend on two classes of factors. On the one hand they are determined by the "external circumstances" under which the individual is placed; these vary from case to case in a somewhat haphazard manner. On the other hand the condition of the individual, as he wends his way through life, is determined also by the progressive biological changes which lead him from childhood through adolescence to maturity and old age. These changes proceed in a regular manner, following in all normal individuals a common law or order, and thus impressing a specific stamp upon human life, and ranging all individuals under one general type.

To each man in his turn, rich and poor alike, regardless of circumstances, are revealed the basic truths of life. The gain in wisdom, which comes with the years, is not a mere accumulation of knowledge acquired through the information carried to us from outside by our senses, but is rather a change in point of view, an evolution from within. The same event is seen in a different light by the young child, living in a world of naïve innocence, by the adolescent, when the blood runs hot and energy abounds, and by the veteran, in whom the lamp of life burns low. This is the romance of life, sung by the poet and represented in our best fiction. For, just as perfection of physical form, the expression of biological haleness, appeals to our æsthetic sense and elicits our homage, so the contemplation of its spiritual counterpart, the "perfect life," in which all human faculties are developed to their highest excellence and perform their functions uncurtailed and untrammeled, speaks to us with its own inspiration. Such perfection is, however, but an artist's ideal, rarely approached in real life. Indeed, the other extreme is perhaps more common, the crippled in body, though undaunted in spirit, who would fain—but cannot—join others in their toil and play; and the cripples in life, who through unheard circumstances is deprived of the opportunity to exercise his faculties to the full; condemned to drag out a colorless existence to the end of his days.

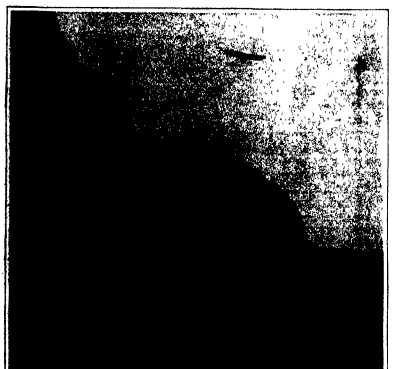
Between these two extremes the average human life is laid. Though each runs a similar thread, as our biological make-up is similar. But the details differ from case to case. To each of us in turn life's story is told. We listen, as to some old melody played with infinite variations, now in a minor key—rehearsing over the same theme, yet never twice the same; now listener, now singer, but ever, and with its last note the spell of life has expired.

Cross-Country Aeroplane Races in Europe

Further Particulars Regarding Recent Record-Breaking Flights

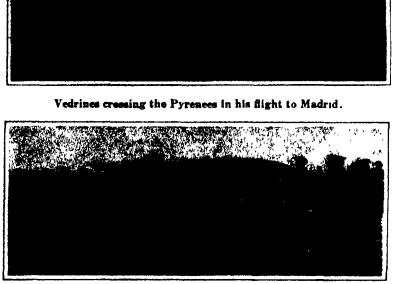
WHAT Vedrines had to fly over in his wonderful flight from Paris to Madrid is graphically shown in the photograph reproduced on this page, for which we are indebted to *The Car*. Flying low over the rugged peaks of the Pyrenees, Vedrines took chances such as only the most daring aviators would take.

Starting from San Sebastian at 7:20 A. M. on the morning of May 25th in a dense fog, Vedrines succeeded in crossing the Pyrenees and reaching Quentana-Pelta, a few miles from Burgos, where he was obliged to repair the damage to his tank and to get aid to place his machine on a suitable field for restarting. He then flew back to Burgos, where he passed the night and made a fresh start at 5 20 A. M the next morning. He covered the remaining 135 miles to Madrid without a stop in 2 hours and 46 minutes, alighting on the aerodrome at 8:06 A. M. amid the applause of thousands of spectators. His total time in flight for the 722 miles was 7 4 hours and 54 minutes, so that he covered the distance from Paris to Madrid at an average speed of 48¼ miles an hour. His total official time, including penalization, was 37 hours 27 minutes 12 1/5 seconds.



The other two survivors, Garros and Gibert, did not fare so well as Vedrines. The former got only 5 miles from San Sebastian when he was obliged to descend because of a motor mishap. He restarted and flew a few miles farther, when he came down at Andoain, where he broke his propeller and damaged his machine so that he was obliged to give up the race. Gibert, after crossing the Pyrenees, landed at Alsasua, near Vitoria, but in restarting his Blériot upset on account of the rough ground and was badly damaged. He made repairs, but was hindered from continuing the flight the next day on account of bad weather conditions.

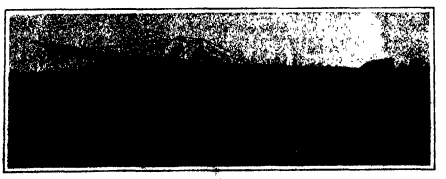
One of our illustrations shows Vedrines on his Morane monoplane just after he alighted at Madrid. The flatness of the wings is very noticeable in this photograph, there being so slight a curvature that it is almost imperceptible. It is due to the flat wings in combination with the 70 horse-power Gnome motor that Vedrines is able to obtain a speed in straightaway flight of about 75 miles an hour. The specifications of his machine appear in the table on the following page. The supporting surface of the wings is 17½ square meters and the spread 9½, while the total length of the machine is 7 meters. The loading is about 6 1 pounds per square foot. Scale drawings of this machine were published in SUPPLEMENT No. 1851. It is one of the most advanced types of monoplanes thus far produced, and probably the fastest with a given horse-power when traveling in a straight line. One noticeable point is the curving of the front edge of the wings at their outer end instead of the rear edge, as with the Blériot. In the Paris-Rome-Turin race Vedrines did not have good luck. He started several days after the others and only got as far as Macon, where his machine was demolished in alighting and he abandoned the race. Gaget and Frey both drove Morane monoplanes with 50-horse-power Gnome motors. The former, when starting at Lasanna, ran into a dog and smashed his machine, which caused him to abandon the race; but Frey, after many mishaps and the substitution of a new machine, succeeded in reaching Rome third in 125 hours and 41 minutes. Count Zbrowski, on his Blériot, was first in 93 hours and 5 minutes, and Conneau second in 106 hours and 14 minutes. Frey was the only competitor who took part in practices in Paris. After making several starts and returning to the aerodrome, on account of bad weather, he at length came to grief in a storm and fell upon marshy land with great force, two arms and one leg being broken and the aviator being saved from instant death merely from the fact that he fell in a soft spot and that he wore a safety helmet. Vidart was the only other aviator in the race to reach Rome. He arrived on his Deperdussin monoplane several days after Conneau and Garros his time for the trip being 171 hours and 13 minutes. The prizes won by the four men who finally arrived at Rome were as follows: Lieut. Conneau, $21,800; Garros, $9000; Frey, $4600, and Vidart, $4000.



One of the new monoplanes that appeared in the Paris-Rome race was the Sommer, photographs of which are reproduced herewith. The three Sommer monoplanes in the race were flown by Kimmerling, Bathlat, and Molla. Kimmerling was delayed at Briguoles for several days. He finally received a new machine and got as far as Cabase (Var), where the machine capsized and was badly damaged. Bathlat got as far as Lyons, where he was obliged to abandon the race. He covered the 68 miles from Dijon to Macon in 54 minutes or at the rate of 75.9 miles an hour. The Sommer monoplanes seem to have met with bad luck and to have experienced considerable motor trouble. One of their pilots took along carrier pigeons with which to send back messages when he experienced breakdowns. Molla flew as far as Vienne, which was the greatest distance traversed by any of these machines. Bathlat's record between Dijon and Macon shows the Sommer monoplane to be a fast machine.

The first great circuit race, and the longest and most popular of all the big cross country flights scheduled in Europe this summer is that known as the European circuit which started from Vincennes on June 18th and includes a double crossing of the Channel with a turning point at London. Nearly $100,000 in prizes were put up, including $12,500 by the London *Standard* for the first machine to arrive at London. There were some sixty-five entries in all, but about fifteen of these cancelled, and when it came to the start of the race thirty-nine machines crossed the line. The first stage consisted of a flight of 212 miles to Liege, with an obligatory stop at Rheims on the way, the second stage was a round trip to Spa and return, a total distance of 37¼ miles, the third stage brought the flyers to Utrecht, 112¼ miles, the fourth to Brussels, 68¾ miles, the fifth to Roubaix, 56¼ miles, the sixth to Calais, 62½ miles, the seventh to London 93¾ miles. The return trip from Calais was made via Amiens, in a straight line to Vincennes, 136½ miles.

The start of the race was as systematic as is the start of a big automobile race. The machines started from three parallelograms at intervals of 2 or 3 minutes. After the gun sounded at 6 o'clock, Tabuteau, on a Bristol biplane, Vedrines on a Morane monoplane, and Bathlat on a Sommer monoplane, were off inside of 3 minutes. It is estimated that a quarter million people witnessed the start and cheered the aviators. Within 20 minutes Tetard, Kimmerling, Lieut. Conneau, Gaget, Garros, Molla, Vidart, Wynmalen, Morin, and Pedrini were on their way. They were soon followed by Biellovncci, Amerigo, Pascal Duval, Bobba, Count Dhesbel, Loridon, Contenes, Charlix, La Bouret, Le Lasseur, Prince De Nissole, Allard, Weymann, Barra, Gilbert, Valentine, Marquis de Romance, Landron, Morison, Bille, Le Martin, Verrep, Euhlind, Balger, and



Vedrines crossing the Pyrenees in his flight to Madrid.

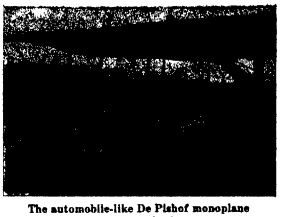
Note the almost perfectly flat wings used on this fast machine.

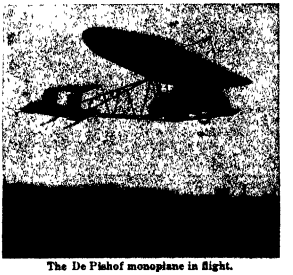
Three-quarter rear view of Sommer monoplane.

Tail of Sommer monoplane, showing flap elevators at rear.



FAST AEROPLANES IN THE EUROPEAN CIRCUIT RACES

last of all, Emile Train, the aviator whose machine killed Mons Berteaux, the Minister of War, at the start of the Paris-Madrid race



Besides the usual number of withdrawals owing to poor starts, the race was marred by three fatal accidents which occurred within a short distance of the aerodrome The nearest of these was the accident to Le Martin, who had had trouble with his rudder and had been advised by Garros not to start. He started twenty-sixth on the list, however, and no sooner was he in the air than it was seen that he had lost control of his machine, which bobbed up and down dangerously He had risen to about 200 feet and was straightening out on his way, when suddenly the machine began to pitch about in a terrifying manner just as he was passing over a patch of woods Le Martin shut off the motor and attempted to glide to the ground, but a gust of wind drove the machine to earth and upset it The aviator was pinned to the ground and his skull was terribly crushed He died a few minutes after he had been taken to the hospital

The other fatal accidents were much more spectacular The first of these happened to Capt Princetau, a young lieutenant who had just been gazetted the day of the race He had been ordered to accompany the racers and was flying at Issy-les-Moilneaux, at a height of some 75 feet, when suddenly his machine burst in flames and dove to the ground So hot was the fire that the captain's fellow officers were unable to get him out of the wreckage, and he was burned to death beneath it. If indeed he was not burned and rendered unconscious before the machine struck the ground

The second aviator to meet a similar fate was Landron, who flew a De Pishof monoplane He was flying above Chateau Thiery at an elevation of about two thousand feet, when his machine burst into flames and fatally burned the aviator during its drop to the ground We reproduce photographs of the De Pishof monoplane in flight and on the ground It

The automobile-like De Pishof monoplane viewed from the front.

The De Pishof monoplane in flight.

Garros in 5 hours and 3 minutes, and Renaux (the only contestant carrying a passenger) in 12 hours and 55 minutes After a rest of two days, during which time ten more of the aviators had arrived at Liege, 14 of them made the flight to Spa and return. On May 22nd the second real stage of 130 miles to Utrecht was flown Vedrines smashed two machines and was obliged to get a third. Seven aviators reached Utrecht in the following order: 1, Gilbert (Blériot); 2, Vidart (Deperdussin); 3, Garros (Blériot); 4, Lieut. Conneau (Blériot); 5, Weymann (Nieuport); 6, Kimmerling (Sommer); 7, Train (Train). All the aviators were bothered by a strong and gusty wind. Amerigo capelsed when ascending at Liege He was thrown out and seriously injured. Renaux and Le Lasseur both fell and the latter was rather badly injured. Duval descended near Venlo, and Barry broke down near Randwyk.

The third stage of the race, 93½ miles from Utrecht to Brussels, was flown on Friday, June 23rd, but no reports have been received of this stage up to the time of our going to press.

Table by courtesy of *Flight*

will be seen that this machine differs materially from the usual type of monoplane It was fitted with a 70 horse-power, 4 cylinder Labor motor in place of the revolving cylinder Gnome which was used on Lieut Princetau's Blériot How these machines came to catch fire in flight, and the ever-present danger of such an occurrence, is discussed elsewhere in our columns

Besides the fatal accidents above mentioned there were several other accidents that were rather serious Lieut Gaubert fell near Soissons and was found lying unconscious in a wheat field Bielle fell within a mile of the start and was badly bruised and Loridan, Morison and Morin also made heavy landings and received a severe shaking up The last named was within twenty miles of Liege when he met disaster The aviators who reached Liege the same day were Vidart, in 3 hours 13 minutes; Vedrines, in 3 hours and 38 minutes, Weymann, on a Nieuport monoplane, in 4 hours and 55 minutes, Lieut Conneau, in 4 hours and 07 minutes; Barra, on a Farman biplane, in 4 hours and 8 minutes, Duval, on a Caudron biplane, in 4 hours and 31 minutes;

LEFEVRE MONOPLANE, SHOWING IMPROPER ARRANGEMENT OF GASOLINE TANK

Arrangement of Motors and Fuel Tanks on Aeroplanes

ON OUR editorial page we call attention to the danger from fire on present-day aeroplanes and make suggestions regarding the location of the gasoline tank in a safer position than one in proximity to the motor. The Gnome motor, which is so widely used on the modern machines, is in some cases surrounded by a steel ring or casing which keeps the oil from flying out by centrifugal force and coming back in the face of the aviator. A section of the ring is missing at the bottom part, for it is at this point that the exhaust valve of each cylinder is open and that the burning gases are allowed to escape into the air. As no carburetor is used in this motor, the gasoline being fed through a jet into the horizontal hollow stationary crankshaft, there is no danger of the machine catching fire from the carbureter in the way we have stated. In Lieut Princetau's case the machine is said to have burst into flames and to have set fire to the aviator's clothing while he was 75 feet in the air. It is difficult to explain how this happened. In all probability there was a gasoline leak near the motor, and the fuel, trickling down through the floor, caught fire from the burning exhaust gases as they shot out underneath the machine. The flames were driven back at the aviator by the speed of the aeroplane through the air, and no doubt the gasoline tank ignited the moment he struck the ground.

One of the illustrations on this page shows the Henri Lefevre monoplane (which is one of the newest French machines) fitted with an 8-cylinder V-type motor The radiators are shown on each side of the body and the gasoline tank above and slightly to the rear of the engine; the carburetor can be plainly seen between the cylinders at the front. This arrangement of the gasoline tank is a very dangerous one and one that should be avoided If by any chance the carburetor should catch fire, the flames would instantly strike the gasoline tank, melt any soldered joint in the piping or tank, and deluge the motor and machine with a flood of gasoline; the result would be a terrific conflagration and the aviator would have no chance of escape. There is also a possibility of an explosion in case the gasoline tank should happen to be only partially filled The arrangement of the tank on the Lefevre monoplane is therefore one that should be avoided.

Turf as a Filter

RECENT experiments in France have shown that natural turf is an excellent material from which to form beds for the filtering of sewage. A volume of between three and four cubic meters of sewage can be purified every day for every square meter of the surface of the turf. A turf filter that has been in use for some time shows no diminution of efficiency. If a larger proportion of sewage than that mentioned is employed the filter proves less effective, but it recovers its power when the amount of sewage is reduced to the proper proportion. Chemical analysis and the effects upon fish put into the filtered water unite in testifying to the efficiency of the process.

Air Consumed in One Minute

IN one minute, in a state of rest, the average man takes into his lungs about 8 liters or 488 cubic inches of air. In walking, he needs 16 liters or 976 cubic inches; in climbing, 32 liters or 1,952 cubic inches; in riding at a trot, 48 liters or 2,928 cubic inches; and in running for a short distance, running, 60 liters or 3,660 cubic inches.

One Hundred and Forty-four Postal Cards per Second

A New Machine for the Public Printer

By Thomas D. Gannaway

WHETHER the government ownership of certain public utilities would be an advantage to the mass of people, is a much mooted question. But Mr. Samuel Donnelly, Public Printer, is thoroughly demonstrating the fact that the government ownership of postal card presses is a case of real economy to the United States Government. Until the beginning of the present fiscal year, postal cards have been printed under annual contract by private concerns. This necessitated a great deal of unnecessary trouble and expense to the Government.

The Government Printery naturally must keep abreast with the rapid growth of the public business. It has, therefore, been enlarged from time to time, until it to-day is the largest printing establishment in the world.

Last year, when bids for the printing of postal cards for the next ensuing fiscal year were asked for, Mr. Donnelly, the Public Printer, wishing to serve "Uncle Sam"—his employer—to the best of his ability, submitted a bid for the job. The printing of the little one-cent postal cards for one year is a tremendous undertaking, and the making up of the bid requires very accurate figuring. It is claimed by the contractor of last year that he lost money. He would not bid for the job again, which is good evidence of the truth of his assertion. When the bids were opened by the department, it was found that the Public Printer was the lowest bidder. There was some criticism at the time on the Government's undertaking to do this work. This must have been due to the critic's lack of knowledge of the ability of the Government Printing Office to do the task. There is no private concern as well equipped to do this job, and do it as economically, as the Government. Again, a private firm, not having any assurance of getting their contract renewed, could not afford to invest in the proper machinery, which must, necessarily, be of a special design, to produce the best results. The private contractors, therefore, were compelled to use the ordinary straight sheet press; while, as may be seen from the accompanying cuts, the Government is using very large rotary presses especially designed for this work. It was thought, until within the last few months, that such work could not be done on the rotary style of press. The use of such press greatly increases the speed with which the cards can be printed, thereby diminishing the cost of them. The two rotary presses now in use have a capacity of over two million postal cards each in eight hours. It would be preposterous to think of an ordinary flat sheet press approaching half of this capacity.

The paper on which the cards are printed is wide enough to allow eight cards to be printed lengthwise across it. Each roll weighs one thousand pounds net. Ordinarily there is great waste in handling this size roll of paper, by hauling it on trucks, standing it on end, tumbling it about from place to place, and incidentally dropping it. In order to prevent this wastage, and at the same time save the expense of handling it so much, Mr. Donnelly conceived the idea of building a structural iron rack to hold the stock of postal card paper. As will be seen from Fig. 1, this rack consists of three tracks, one over the other. At either end of it is an overhead track, on which is mounted a portable lift.

A large ball-bearing truck, drawn by two horses, is used to haul the paper from the freight station. It carries six rolls, or seven hundred pounds gross weight, of a load. A load is pulled up to the entrance to the loading card department, where the overhead track referred to extends out over the driveway; then the portable lift is run out over the loaded truck, a piece of three-inch pipe is run through a roll of paper, the lift is hooked onto each end of the pipe, and, although the roll weighs eleven hundred pounds, one man hoists it up and runs the lift back to the end of the rack, where the roll of paper is swung around into place. Small two-wheel trucks are placed under each end of the three-inch pipe and on a monorail on each side of the rack, then pushed on to make room for the next one. This rack is two hundred and ten feet long and has a storage capacity of two hundred and eighty thousand pounds of paper at one time. When one deck of the rack is filled, a large cable which extends from the delivery end to the receiving end and back is thrown over the whole row on that deck, and by winding up one end of it the rolls of paper are pulled down to the delivery end as they are needed. Overhead lifts, the same as are used to unload the trucks, are used to transfer the paper from the rack to the presses, as shown in Fig. 2. The roll is picked up out of the rack in the same way as it is lifted off the truck, and is carried to the press. It is then let down on the floor and the chock is fastened in it, the roll is then again picked up by the lift, and by means of a switch in the overhead track it is carried and put in its exact place on the press. After the roll has been placed in the press, the wrapper is removed and the end of the paper is attached to that already in the press by means of a piece of adhesive tape, thus practically eliminating all wastage at the start. Notwithstanding the fact that the paper is wound on large metal cores there are several rounds which cannot be used successfully on rotary presses. Ordinarily this would be wasted, but it is stripped off, cut into sheets of a certain size and used for making other official cards which the Government has to have. Thus the wastage is practically nothing.

Fig. 1.—This rack is 210 feet long and holds 280,000 pounds of postal card paper.

Fig. 2.—The two card-printing presses with a capacity of nearly two and one-half million postal cards per day.

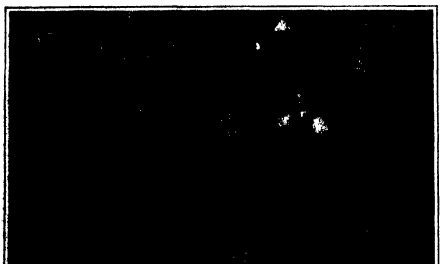

Fig. 3.—Press for printing reply cards.

Each press has two cylinders, containing several cuts each, from which the cards are printed. The two cylinders make it possible to print the reply postal cards—which must be printed on both sides—at one operation. When the ordinary postal card is printed, only one printing cylinder is used. The press shown in Fig. 3 is printing the reply cards. These are automatically cut, leaving one message and one reply card attached together. When the paper has passed over the printing cylinder it passes under a slitter, which trims the outer margins and slits the paper into eight strips, just as wide as one postal card is long.

These strips then pass under a cutter which strikes them at a speed of no less than nine strokes per second, cutting eight cards at a stroke, making seventy-two cards per second. When printing the reply cards the cutter is so adjusted as to make just half as many strokes per second. The cards are dropped in eight stacks, until these contain twenty-five each, then they are automatically carried out on the receiving table, where there are eight attendants to receive them. Each of them takes a pack, fastens a paper band around it, and drops it in a box. When the packs are coming at the rate of eight every three seconds, it is easy to see that there is no time to lose. Mr. Donnelly tells me that two machinists are working on an attachment for these presses which will strap the packages automatically. When this is completed it will diminish the cost of producing the cards several hundred dollars per year.

It has been the custom of the Post Office Department to ship the cards to large offices in wooden boxes holding ten thousand cards. They now use containers made of cardboard. By weighing we found that the one made of wood weighed ten and three-fourths pounds, while the one made of cardboard weighed one and seven-eighths pounds. There are about ninety thousand of these containers used per year. Thus the Government is saved the transportation charges on eight hundred thousand pounds of supplies carried in one year. The containers are filled and sealed near the press then stacked on a portable platform. When the platform contains as many packages as one man can readily haul on a four-wheeled truck, the truck is backed under it, and by turning a crank at one end certain parts of the truck floor are forced up at each corner, thus lifting the loaded platform off its supports and letting it rest on the truck. It is then taken to the shipping room and let down on other supports, thereby saving the time of at least two laborers.

WEIGHT.—The weight asked for was to cover "all essential parts, including carburetor, ignition system, lubricator, radiator, ready for fuel to start." The figures printed are those given us under this condition, unless otherwise specified in table

BLANK.—Dotted lines are used where information has been requested and not supplied.

A. L. A. M. RATING.—The A. L. A. M. formula is bore squared, times the number of cylinders, divided by 2.5. The result times 1¾ gives one rating, used above, for 2-cycle engines.

* rotating motors † The Elbridge Company makes six sizes as does the General Machinery Company †† This is also made in 50, 70 and 100 horse power sizes ‡ Made also in 60, 70, 100 and 150 horse-power sizes.

‡‡ Other sizes are 40 and 60 horse-power. The same sizes are also made in four-cycle engines.

Campaniles, Medieval and Modern

The Bankers' Trust Building—Successful Solution of a Difficult Architectural Problem

FREQUENTLY during the past few years the SCIENTIFIC AMERICAN has drawn attention to the fact that, since the modern "sky-scraper" office building has been carried up to a height which renders it nothing more nor less than a tower, the architect should treat it as such and accentuate, in his treatment of the exterior, the vertical at the expense of the horizontal lines. Frequently in earlier designs the opposite course was followed, and an attempt was made to reduce the appearance of height by running across the façade at regular intervals heavy, projecting, cornice-like bands of masonry, thus giving to the building the appearance of a series of separate structures mounted one above the other. The result was deplorable.

In the more recent tall buildings, however, our architects have frankly accepted the situation. In some cases they have taken the medieval campanile as their model, in others, they have obtained successful effects as seen in some of the competitive designs shown at architectural exhibitions, by embodying, in a broad way, the principal elements of the classic column—base, shaft, capital, frieze and cornice.

The most recent of the "tower" buildings to be erected in this city is a magnificent pile of steel and granite which stands at the corner of Nassau and Wall streets, and will be known as the Bankers' Trust Building. From a base approximately 95 feet square it rises in an extreme height of 540 feet above street level. The proportions and outline of the structure are those of the medieval campanile; the details are pure Greek, and the combination has been so successfully carried through, that we believe it will be the general consensus of opinion that the architects, Messrs. Trowbridge & Livingston, have produced in this structure the most harmonious and dignified building of its type in this or any other American city. Particularly are they to be commended for heightening the æsthetic appearance of the structure by abolishing all windows from the pyramidal structure which forms the huge capstone of the tower, and carrying up the stone work in a series of massive steps rather than in plane surfaces. The many-windowed pyramid is an anachronism of the most painful kind; whereas the stepped surface is perfectly harmonious with classic ideas, being suggestive, indeed, in the present case, of the ancient mausoleum of Halicarnassus.

By way of accentuating at once both the similarities and the differences between the medieval and the modern campanile, our artist has imposed his drawing of the Bankers' Trust Building upon a photograph of the famous St. Mark's Square, Venice. The modern building has been placed at the same distance from the eye as the old Venetian campanile, so that the two appear upon the same scale, and the observer receives a just impression of their relative heights and other proportions. The Venetian tower stood 323 feet in height upon a base which was approximately 42 feet square. It will be noted at once that the pyramidal portion of the Venetian tower has a much steeper inclination; in which respect the pyramidian of the Metropolitan Building follows more nearly the Venetian model. The inclination of the Bankers' Trust walls is 70 degrees, and that of the mausoleum of Halicarnassus was 45 degrees. We think it will be agreed that the architects have adopted a judicious compromise.

Before passing to a description of the engineering and constructional features of the building, it is well to mention here that the preparation of the site involved the purchase and complete removal of the Gillender Building, built less than fifteen years ago, a modern eighteen-story steel-and-stone structure, which stood on a limited plot at the corner of Nassau and Wall streets. For the reason that its rentable floor surface was too greatly reduced by the elimination of the space necessary for elevators, stairways and corridors, this building had never been a paying proposition. To allow the old building to stand and carry the new structure around it in the form of an L, would have been to cut out the major portion of the light and air—elements of prime importance in determining the rentable value of a modern office building. It took only a few minutes figuring with pencil and pad to prove that it would be a more profitable investment to buy and destroy this eighteen-story steel building, and erect a new thirty-story structure upon the whole corner plot, 97 by 94¼ feet, thus secured.

Alike in the wrecking of the old building, the preparation of the foundations and the erection of the new structure, all previous records for rapid work have been surpassed, as the following dates will show. The wrecking of the Gillender building was commenced April 29th, 1915. Forty-five days later it had disappeared. On June 15th work on the foundations commenced; and on November 1st, 1915, the first steel columns of the new building were erected. By June 6th, 1916, the steel work had been carried to complete to its full height of 502 feet above the foundation footings, and by September 1st, the stone work will have been finished also. The erection of the stone work, by the way, has been particularly rapid, the average rate of progress having been 3½ stories per week. Such expeditious work was made possible

to three causes; first, that all office work upon plans, etc, has been done far in advance of the building, this being true of the smallest details; secondly, that the granite work, even to the cutting out of the checks to receive the projecting portions of the steel, was completed before the stone was shipped to the site; and, thirdly, that the contractors, Marc Eidlitz & Sons, had perfected an organization by which material was brought to the building only as it was required and always slightly in advance of the demands of the erectors.

We dwell at some length upon this feature, since it is largely in standardization of materials, accurate shop work, and highly specialized organization of the erection forces at the site, that American architects and builders have succeeded in prosecuting their work at a speed which is not approached in any other part of the world. As an instance of high-class erection, it may be recorded that the work of Post & McCord, who had the contract for the steel, was so accurate that the columns, in the course of their progress to a total height of nearly 600 feet, have not varied more than a quarter of an inch from the plumb line. That this speed of erection has not been due to reckless haste is shown by the fact that it was marked by but one accident.

Although, architecturally speaking, the chief interest in this building is to be found above street level, its interest from the engineering standpoint lies in the work which has been done below the sidewalk, in preparing the foundations. Here a system has been adopted which the architects believe is destined, because of its many advantages, to become standard practice in lower Manhattan. The old method of preparing foundations was to sink concrete-filled caissons through the water-soaked sand and silt, which overlie the bed rock, and erect upon these the footings for the steel columns. Usually a caisson was sunk for each line of columns. These caissons which would be anywhere from 8 to 25 feet in their largest diameter, naturally occupied a large amount of the valuable space below street level, which is used for basement, engine room, storage and other purposes. Furthermore, there were objections to this method, due to the difficulty of waterproofing and excluding moisture from the steel footings of the columns

The new system, as adopted in the Bankers' Trust Building, is to sink a continuous steel-and-concrete cofferdam wall entirely around the plot on which the building is to be constructed, extending the wall everywhere down to solid rock, with which it forms a water-tight contact, and carrying it up everywhere above water level. When the wall, which is 7 feet in thickness throughout, had been completed, the sand and silt and the caissons of the old Gillender Building were removed, until the underlying rock was exposed. During the progress of excavation a framework of heavy timber struts was built from wall to wall, for the purpose of counteracting the outside pressure of the water-soaked silt, which reached a maximum of 3,360 pounds per square foot. When the excavation had been completed, the footings for the foundations of the steel columns were prepared, and the erection of the steel skeleton commenced. On the sides of the plot contiguous to existing buildings, the columns were erected upon the cofferdam wall. On the sides abutting on the streets, the footings were placed on the solid rock contiguous to the wall.

The advantages of this system of construction are several. In the first place, the steel work is open to inspection right down to the mother rock. In the second place, the exceedingly valuable space below the sidewalk is rid of the cumbersome caissons, whose place is taken by the comparatively slight bulk of the columns. It is the belief of Mr Trowbridge that ultimately, on the reconstruction of the city, whole blocks will be syndicated, and a continuous cofferdam wall will be run around each block. This will result in a great saving in foundation work, the columns springing, as in the Bankers' Trust Building, directly from bed rock, while the heavy interior partition walls which now separate the various buildings on a given block will be unnecessary, and light partition walls will take their place.

It can readily be seen that should a whole section of the city be thus founded, the space below the streets, between caisson walls of opposite blocks, would form an admirable three or four story subway, in which to place city traction lines, and carry the gas and water mains and the electric cables for light and power purposes.

By embedding in the horizontal framing steel girders of sufficient depth and section, the bending stresses due to wind pressure have been provided for. Moreover, the inertia of the great mass of the building, whose total weight is approximately 50,000 tons, will absorb the shock of the heavier gusts of a thunder storm or tornado.

The interior finish of the building is thoroughly fireproof. No wood whatever has been used. The doors are of steel, and the trim, window sashes, etc, are also of metal. Granolithic floors with marble base-boards, have been laid throughout Wire-plate glass has been used everywhere in interior partitions. In the basement are powerful fire pumps, and large tanks have been installed in the roof The use of the pyramidal roof structure entirely for storage purposes is a novel feature. It is reached by elevator, and each of its seven floors is provided with an interior gallery, from which burglar-proof doors open into the several storage rooms thus provided It is a curious fact that, although lower Manhattan is so abundantly provided with safe-deposit vaults, there is not a single storage warehouse in which bulky materials, such as office furniture, can be placed for safe keeping

The total cost of the building is about $4,000,000. Its location in the very heart of the Wall Street district, and its advantages of light and outlook, have combined to raise its rental to the highest figure yet recorded for commercial buildings of this type.

An American "Comptes Rendus"

THE *Comptes Rendus Hebdomadaires*—the pink-covered weekly organ of the French Academy of Sciences, so familiar to every scientific man—is an epitome of the progress of science in France Its cardinal virtue is conciseness A *savant* will spend years in elaborating some epoch-making discovery—and announce the same in a laconic page or two, confident that his announcement will presently be read in every corner of the world.

Although in America we have no intellectual metropolis in the same sense that France has, yet our political capital—the seat of the great scientific departments of the government, and of the Smithsonian and Carnegie institutions—holds a somewhat analogous position It therefore appears fitting that the Washington Academy of Sciences—the focus of the scientific community at the capital—has undertaken to publish what promises to be a sort of American *Comptes Rendus* This publication, the *Journal of the Washington Academy of Sciences*, will appear semi-monthly, beginning July 15th, 1911, and will replace the *Proceedings* of the same academy, than which it will have a far wider scope.

In the new publication will be recorded the results of all kinds of scientific work carried on by the Government, as well as by non-official institutions and individuals at Washington, or connected with the scientific organizations of that city Each scientific bureau of the Government has been asked to designate some one who will forward to the editors such material as the bureaus are willing to have published in this way. This material may take the form of preliminary statements concerning work nearing completion, abstracts (preferably by the authors) of papers recently published by the bureaus, or complete short articles. The journal will also contain notes of events connected with the scientific life of Washington.

The editors responsible for the successful inauguration of this new enterprise—which is viewed with deep interest by scientific men, in and out of the capital—are G K Burgess, of the Bureau of Standards, B. W Evermann, of the Bureau of Fisheries, and F. L. Ransome, of the Geological Survey.

The principal function of the new journal will undoubtedly be to place before the world, in a concise and easily accessible form, the cream of the information now consigned to a host of official publications, most of which fail to reach a majority of the readers who would find them of interest

Asteroid Notes for the Month of July

OF the asteroids, Vesta is too near the Sun to be seen during the month of July Below we give the ephemeris for Pallas, Ceres and Juno Several have written that they have succeeded in finding one or more of the small planets by the aid of the ephemeris given heretofore. Usually a really good pair of field glasses or a small telescope is all that is needed. For one who has not as yet succeeded in finding one of these, our small neighbors, we suggest that a good pair of field glasses be used and an asteroid selected that is of good magnitude and favorably located. Possibly Ceres will be as good as any for the month of July. It is under the ninth magnitude, constantly growing brighter, and very close to Zeta Tauri on July 15th about 2 A M. At this time the R. A. of Ceres is 5 hours 32 minutes, and its Dec. is +22° 18'. The R. A of Zeta Tauri is 5 hours 32 minutes, and its Dec is +21° 6'. So Ceres will be one degree directly north of Zeta Tauri at this time.

Pallas should be easily found. During the last days of June it moves directly north of Delta Ceti, and by July 1st forms a small triangle with Delta and Gamma Ceti. By the close of the month it passes just to the north of 91 and 95 Ceti. Pallas is also in the morning sky during July.

Juno is still growing fainter—of the 10.5 magnitude on July 11th. However, it is no near Delta Virginis on July 4th that it should be easily seen in even a moderate sized telescope It will be remembered that on April 28th it was very close to this same star (See ephemeris and notes in SCIENTIFIC AMERICAN for April 1st) The R A of Delta Virginis is 12 hours 51 minutes, and its Dec. 3° 52' N. On July 4th the R A of Juno will be 12 hours 51 minutes, and its Dec 3° 41' In other words, it will be about a sixth of a degree south of Delta Virginis On April 28th it was one-tenth of a degree due north of it. It is interesting to note its course during these last months Note the ephemeris for April and follow its motion on the star atlas. It continued to move south till June 1st, when it was stationary, with an R A of 12 hours 41 minutes and a Dec. of N. 5° 10'. It is now retracing its steps exactly.

Title Pages for the Scientific American

THE present number of the SCIENTIFIC AMERICAN marks the beginning of a new volume Contrary to our practice in former years, we have not included the usual volume title page Those of our readers who wish to bind up the last volume will receive a title page on application to this office

The Current Supplement

THE opening article of the current SUPPLEMENT, No 1852, deals with the new Campanile at Venice —Dr. L A Bauer describes some of the problems of ocean magnetic work.—A remarkable paper was recently read by Major George D. Squier before the American Institute of Electrical Engineers, on "Multiplex Telegraphy and Telephony by Means of Electric Waves Guided by Wires" This paper is published —The fourth installment of Sir J J Thomson's brilliant Royal Institution lectures on "Radiant Energy and Matter" finds a place in the current SUPPLEMENT— Other articles of interest are the following "The Principles of Original Research," by Prof Sedgwick Minot, "The Sun's Distance," by Prof J H Ogburn; "An Important Report on Sewage Disposal Investigations", "Some Recent Types of Aeroplanes", "Some Recent New Inventions", "Chemical Research and Industrial Progress," and "A New Spectroscope and Spectrograph."

Cork Varnish for Ships

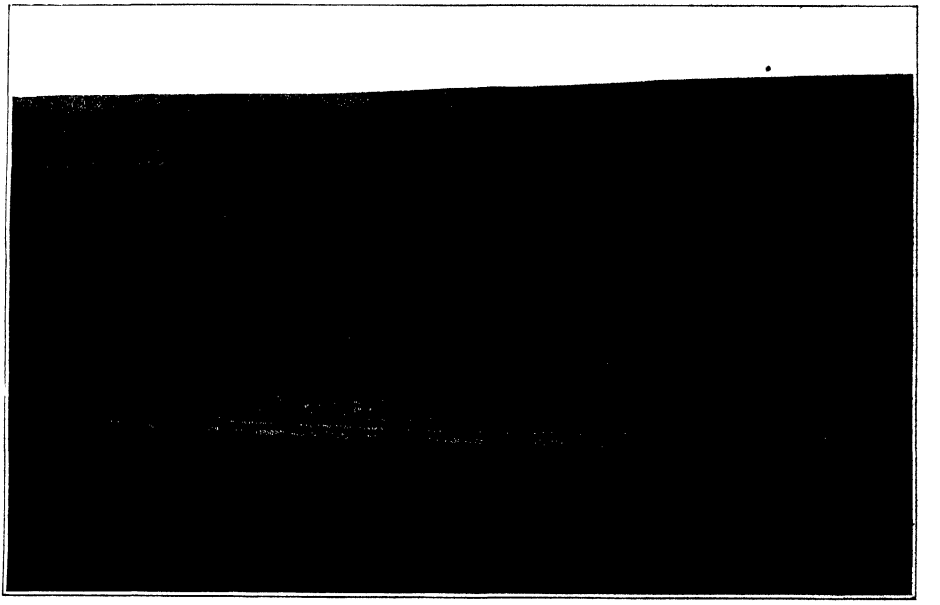
IN order to protect the interior of ships from the humidity caused by condensation upon the metallic walls during sudden changes of temperature, the Italian marine has experimented with a kind of hygroscopic varnish, or coating, the essential compound of which is ground cork, which is consolidated by pressure with copal and litharge, and applied to the walls It has been found that the cork varnish absorbs the watery vapor of the atmosphere to the extent of eight or nine grammes for every square meter of surface exposed.

A Gasoline Tool Car for Railways

THE Chicago and Rock Island Railroad is using a gasoline car to convey men and tools to any point where repairs or construction work are needed The car not only transports tools and men but supplies the necessary power for operating electric tools A 30 horse-power, 4-cylinder, 4-cycle gasoline engine drives a generator which supplies power for operating electric tools. These tools are Two electric spike screwing machines, six electric drills, one electric saw for rails, and portable emery wheels The car can carry 8 to 10 men and any reasonable equipment of tools.

The New White Star Liner "Olympic"

A Ship 882½ Feet Long, That Weighs When Fully Loaded 66,000 Tons



THE arrival of the White Star liner "Olympic" at New York sets another mark in the growth of the modern ocean liner toward the ship one thousand feet long The story of the development of the trans-Atlantic liner is full of interest, and it is worthy of note that until of late years, the growth in size and speed, if we except the case of the "Great Eastern," has been by regular and fairly even advances Thus the "Britannia," of 1840, 207 feet long, had an average speed of 8 5 knots per hour The "Asia," of 1850, 266 feet long, and of 12 5-knot speed, had a gross tonnage of 2,226. The "Scotia," of 1862, 379 feet long, and of 14.4-knot speed, had a gross tonnage of 3,871 The "Bothnia," of 1874, was 420 feet long, had a gross tounage of 4,556 and a speed of 13 8 knots The "Servia," of 1881, 515 feet long, was of 7,392 gross tonnage, and her speed was 16 7 knots The "Ivernia," one of the type of mixed cargo and passenger ships of moderate speed, which have now become so popular, launched in 1900, was 580 feet long, had 14,027 gross tonnage, and a moderate speed of 15 25 knots The "Campania," 600 feet long, of 12,952 tons gross tonnage, with a speed of 22 knots, launched in 1893, was the first vessel to reach a length of 600 feet between the perpendiculars The "Coronia," launched in 1905, was 650 feet long, with a displacement of 20,000 tons The first ship to exceed a length of 700 feet was the White Star liner "Oceanic," whose length on deck was 704 feet Then followed the "Lusitania" and "Mauretania," 790 feet in length, of 53,000 gross tonnage, with respective sea spee of 25½ and 26 knots per hour, both of which ships made their appearance about 1907 And now, in the "Olympic" and the sister ship "Titanic," we have the first vessels to exceed a length of 800 feet, reaching, indeed, almost to the 900 feet length while their gross tonnage has gone up to 45,324, and their displacement at maximum draft has reached 66,000 tons

Although the "Olympic" is not so fast a vessel as the "Mauretania," she is capable, when pushed, of a speed of 22 knots and, like those vessels, she is, to all intents and purposes, a purely high-class passenger ship Although it is possible to stow in her hold about 6,000 tons of freight, it is rarely that she will carry more than about 2,000 tons, for her time in port will be almost entirely given up to coaling and getting ready the accommodations for her complement of over 3,000 souls, and caring for the engines and boilers necessary to enable her to develop her maximum horse-power of 50,000.

On this, her maiden voyage, she left Southampton at noon on Wednesday, June 14th, called at Cherbourg and Queenstown, and left Queenstown on Thursday. She was at her dock early on Wednesday morning, having completed the trip from Southampton at an average speed of 21 17 knots As she steamed majestically up the North River, and warped in alongside of her pier, the "Olympic" looked every inch of her length and height, and fully came up to the expectations which had been raised by the published description of her vast dimensions What these are may be gathered from the following figures: Length on deck, 882½ feet; breadth, 92½ feet, breadth over boat deck, 94 feet, height from keel to boat deck, 97 feet 4 inches. At a draft of 32 feet, which the vessel drew on entering the harbor, the height of the boat deck above the water line is 62 feet 4 inches The height from the keel to the roof of the captain's house is 105 feet 7 inches, and from the keel to the top of the funnels, 24 feet in diameter, 175 feet. Including the floor of the ship at the double bottom, the vessel has 11 steel decks, and her molded depth, that is, the depth to which the solid steel plating of the hull is carried up and broken, is nearly 70 feet, or fully one deck deeper than that of any previous ship. Her gross registered tonnage is 45,324, and her net tonnage 20,894. When the ship is fully loaded to her maximum possible draft, she will displace, or weigh, 66,000 tons

Now, in view of the fact that the "Olympic" exceeds the "Mauretania" by only 92 feet in length and by 4½ feet in breadth, the fact that her displacement is nearly 50 per cent greater, or 66,000 tons against 45,000, needs some explanation. The greater displacement is due to the fact that the model of the "Olympic" is very much fuller, her sides for several hundred feet amidships being practically parallel—the hull, indeed, consisting of a long, parallel body, with a rather fine entrance and delivery. This form is admissible in a vessel of 21 to 22-knots speed; but when we come to vessels driven at from 25 to 26 knots, as are the "Lusitania" and the "Mauretania," fineness of form becomes a prime consideration. It is a fact that there is scarcely a straight line to be found in the underwater body of the two Cunard liners. This fining down of the hull reduces the displacement, and hence the wide difference in the figures for the White Star and the Cunard vessels.

The maximum horse-power of the "Olympic" is 50,000; that of the "Mauretania," 80,000. This disparity in horse-power is perfectly in keeping with what we have said regarding the form of hull, displacement, and speed of the two ships. High speed, after 21 knots has been passed, is obtained only by a large addition to the horse-power, which, for the same vessel, increases as the cube of the speed. Hence, in spite of the finer lines of the "Mauretania," it takes 80,000 horse-power to drive her 45,325 tons of weight through the water at 26 knots, as against 50,000 horse-power to drive the 66,000 tons of the "Olympic" at 21 knots As a matter of fact, the speeds quoted could be obtained only on smaller draft and lighter displacement, say about 40,000 tons for the "Mauretania" and 58,000 tons for the "Olympic."

Length, 882 1/2 feet; beam, 92 1/2 feet; molded depth, 70 feet; displacement on maximum depth, 66,000 tons; horse-power, 50,000; maximum speed, 23 knots; passengers and crew, 3,200.

ARRIVAL OF THE WHITE STAR LINER "OLYMPIC" AT NEW YORK

The weights of various parts of the "Olympic" necessarily run to large figures. The largest plates on the hull weigh 4½ tons; the rudder weighs 100 tons; the anchors, 15½ tons each; the center propeller, driven by the turbine engine, weighs 22 tons, and the two wing propellers, driven by reciprocating engines, weigh 38 tons each. The weight of each link in the anchor chain is 175 pounds.

The engine room plant of the "Olympic" embodies the latest ideas in marine engineering. Steam from the boilers is expanded down through the higher ranges of pressure in two reciprocating engines, each driving its own propeller. From the reciprocating engines the steam is led to a large low-pressure turbine, which drives directly a central propeller. This combination secures a more economical use of the steam than is possible with an all-turbine plant. Moreover, it per-

make the several propellers to be driven more nearly at their best economical speed. It is known that the "Mauretania" consumes about 1,000 tons of coal per day; it is not probable that the "Olympic" will burn over 700 tons per day, if, indeed, she does not come below that figure.

Naturally, a ship of this great size has accommodation for a small townful of people (3,356, as a matter of fact), of whom 750 are accommodated in the first class, 550 in the second, and 1,200 in the third; while the balance is made up of 63 officers and sailors, 322 engineers and firemen, oilers, etc., and 471 stewards, waiters and other members of the commissary department.

An interesting structural feature in the ship is the special provision which has been made for strengthening her long hull to resist the heavy bending stresses to which it will be subjected when driving into a heavy sea and riding over the waves. Some years ago, in our issue of November 10th, 1900, we made a study of some of the possible features which would be incorporated in the future four-day liner, should such a 30-knot ship ever make its appearance. We found that, to give a ship of the great length required sufficient longitudinal strength, it would be necessary to run a plate girder on bulkhead through the center of the ship for several hundred feet amidship, with extra thickness of plating at the top and bottom of this girder, and also at the top and bottom of the shell plating of the vessel. It is interesting to note that the "Olympic" has been strengthened by running four longitudinal girders through the ship for this same purpose, girders extending from the keel up through several decks.

Although we are mainly concerned with the technical features of the "Olympic," this article would be incomplete without some reference to the unusual accommodations provided for the comfort and entertainment of the passengers. In the first place, the deck accommodations are superb, the boat deck, between 60 and 70 feet above the water, being singularly free from ventilators, deck engines and similar obstructions. The bridge deck promenade alone is 550 feet long, and other promenade accommodations through the ship are in proportion. The main dining saloon, which extends the full width of the ship, is over 90 feet wide by 114 feet in length, and it can seat 532 people. Beyond, and really forming a part of it, is a spacious lounge where passengers may assemble before entering the dining room. A notable feature in this room is the nine of the windows, each of which is lighted by two large port holes, one above the other, the light being softened by passing through leaded windows. The main lounge, finished in light oak, is a superb room in the Louis XV. style, measuring 62 by 60 feet; and rivaling it in its proportions and magnificence, is a smoking room of equal size. A notable feature in these rooms is the use of large bay windows, filled with leaded glass, which strongly accentuates the effect which they produce of being large apartments in some stately manor house of the older countries. A swimming pool 32 feet long, a racquet court 30 feet long, and a very complete gymnasium, are among the features provided for the recreation of the passengers. Lastly, mention should be made of the 69 separate suites of apartments, decorated in the Empire, Louis XV., Georgian, Queen Anne, and Dutch styles, which are available for the use of those passengers who are willing to pay from $1,250 to $2,250 for the privilege of occupancy.

An Important Contribution to the Nitrogen Problem

IN many soils the amount of nitrogen present is the factor that limits the size of the crop of grains, potatoes and other non-leguminous plants. Not only is the size of the crop limited, the plants growing on such soils have a lower percentage of protein than the same kinds of plants grown on soils with an abundance of nitrogen in suitable combinations.

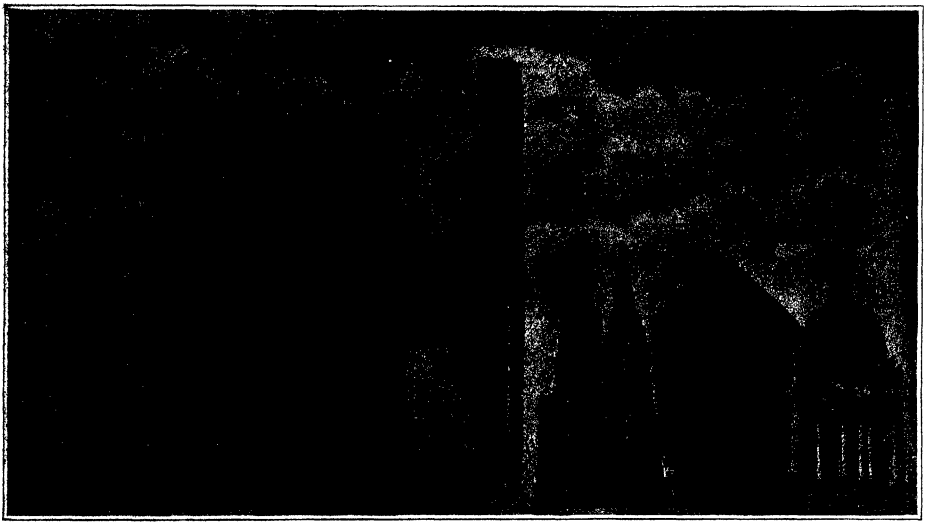
Experiments conducted during the past few years at the Cornell University Agricultural Experiment Station by T. L. Lyon and James A. Bizzell have shown that in addition to restoring to the soil a quantity of nitrogen compounds, which are later available for other crops, the growth of legumes may also furnish nitrogenous food to other plants growing with them, and then influence the nitrification of the soil besides.

The following table combines the results of several experiments:

TABLE SHOWING THE PERCENTAGE OF PROTEIN IN GRAIN CROPS GROWN ALONE AND WITH LEGUMES

Grain grown alone (Grain crop)	Percentage of protein		Grain grown with legume (Legume)
Timothy	12.75	15.56	Alfalfa
Timothy	9.00	9.69	Alfalfa
Timothy	17.19	24.58	Red clover
Oats	12.69	13.44	Peas
Oats	14.94	16.19	Peas
Oats	10.50	14.06	Peas

In earlier experiments the yield of the soil that had borne one or more crops of legumes was compared with soil upon which plants of this family had never been grown before. In the present experiments the two kinds of plants were sown together. A comparison of the total yield is shown in the next table, wherein are compared the pounds of hay per acre when oats was grown alone with the yield of hay when oats was grown with peas, on two different soils:



POUNDS OF HAY PER ACRE

Oats alone	Oats and Peas
3,750	4,850
2,900	3,900

Other tables in the original paper show the total proteins per ton of yield to be likewise in favor of the grain raised in combination with the legume. The increased protein content of the hay makes it of greater food value.

On certain plots alfalfa was grown for five years; on others with the same kinds of soils, timothy was grown for five years. At the end of this time there was found a larger percentage of nitrates in the alfalfa soil than in the timothy soil, as was to have been expected. But on similar plots which were kept bare for a season after the removal of the plants the same differences were observed. This suggested that nitrification continues after the removal of the alfalfa, and actual experiments with samples of soils in flasks showed that such is really the case. The rate of nitrification, or of converting ammonia into nitrates, is of great importance in agriculture, since it determines the amount of nitrate that will be available for the crop. Samples of soil were tested for the nitrates present, weighed quantities of ammonium sulphate were added and the nitrate test again repeated after ten days. In every case the soil that had borne alfalfa showed greater nitrification than soil that had not borne a leguminous crop. At the end of twenty days all of the ammonia had been nitrified in all of the soils. In other words, the rate of nitrification is decidedly influenced by the fact that alfalfa had been grown on the soil.

The effect of liming upon soils with and without legumes was also studied, and the advantage of liming shown to lie in the influence it has upon the rate of nitrification.

Bunker Hill Shaft. | Philadelphia City Hall. | Washington Monument. | Metropolitan Tower. | Woolworth Building. | S. S. Olympic, 882¼ Feet. | Cologne Cathedral. | The Great Pyramid. | St. Paul's, London.

COMPARISON OF THE "OLYMPIC," 882¼ FEET IN LENGTH, WITH SOME TALL BUILDINGS OF THE WORLD

The Largest Radiator in the World

HIGH-POWERED motors require large radiators, and Consul General T. St. John Gaffney of Dresden describes what is termed the largest radiator in the world. It is intended for the 300 horse-power motor of an airship, is made of aluminium, is 4 feet 7 inches high, 4 feet 7 inches broad and 8 inches deep. Its economy of operation is indicated by an hourly capacity of 6,868 gallons and a radiation of not less than 288,000 calories per hour, while 1,695,000 cubic feet of air pass through it. Its weight is: Empty, 145 pounds, and 209 pounds when full of water.

The Heavens in July

Motions of Stars in Corona Borealis; Two Remarkable Double Stars; the Planets in July

By Henry Norris Russell, Ph.D.

CORONA Borealis—the Northern Crown—though not one of the brightest constellations is conspicuous enough to deserve inclusion in our list of initial illustrations. It is very easy to recognize. The semicircle of seven stars, on the line joining Arcturus and Vega, and nearer the former, cannot be mistaken for any other configuration, and stands out among the neighboring stars clearly enough to convince us that this is a natural constellation—if we may so speak—and not merely a group with arbitrarily assigned boundaries.

It has also the somewhat unusual distinction of bearing some resemblance to the object for which it is named. Though much less complete than the wreath of oak leaves which our initial represents, its form certainly suggests a wreath or crown of some sort.

The first really astronomical question which a look at this group suggests is: Are these stars really near each other—comparatively speaking—and arranged along a semicircle, or is their apparently *symmetrical grouping* merely an effect of chance?

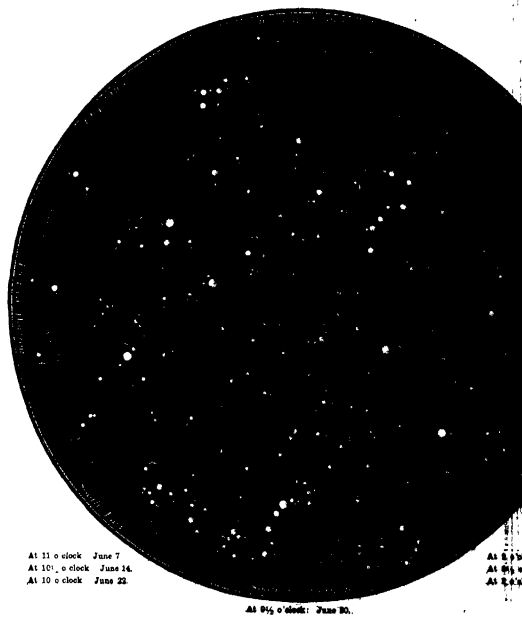
That the latter alternative is the true one is shown by a study of their proper motions—that is, of the motions, apparently slow but really rapid, which the stars themselves possess in space.

No two of the seven stars composing the circlet are moving in the same direction, or at the same rate. The two brightest, Alpha and Beta Coronae, are moving in opposite directions and have nearly exchanged places in the past fifty thousand years (which is a short time in the history of a star). At an equal interval hence, they will be apparently three times as far apart as they are now, and some of the other stars will also have moved so far that the group will bear no resemblance at all to its present aspect.

It may seem a bold prophecy to predict at all what a constellation will look like after so long a time, but the change in a star's position which would be necessary to alter the appearance of the group to the naked eye is several thousand times as great as the amount which can be detected by accurate measurements with suitable telescopes. We have accurate observations of these stars covering over a century and from these their motions can be determined, and their positions predicted, even a thousand centuries hence, more accurately than naked-eye estimates could determine them then.

Some of the individual stars of the group deserve mention. Their real brightness, and their distances from us, presumably vary as much from star to star as do the directions and rates of their proper motion. For only one of the brighter stars do we have any trustworthy determination of these quantities: the brightest of all, sometimes called *Gemma*, which belongs to the group of stars which also includes Sirius and several of the brightest objects in Ursa Major (a description of which was given in our issue of April 2nd, 1910). Its distance appears to be about seventy-eight years, and its actual brightness some sixty times that of our Sun.

There are several interesting double stars which deserve our notice. Two are rapid binaries. One of these, Gamma Coronae, which lies next to *Gemma* on the east, is too close and unequal a pair to be separated by any but powerful telescopes. The other, Eta Coronae, may be found by drawing a line from *Gemma* through the next star to the westward, and carrying it on about two-thirds as far again. This fine and nearly equal pair is now at its greatest separation (about 1 second), and can be seen double with five inches or more of aperture. The period is 41½ years, and three revolutions have been completed since the first observation by Herschel in 1781.



Observers with smaller instruments will find objects of interest in ν and σ Coronae—two small stars, not shown on the map, but easily picked up near the intersection of lines drawn from β through ζ Herculis, and from η Herculis to α Coronae.

Sigma Coronae, the westernmost of the two, is a binary of long period—350 years or more. The components, of the 5th and 6th magnitudes, are now 5 seconds apart, and can be separated by a small telescope.

Nu Coronae, the eastern of the two, is a very wide double, separable even by the naked eye, and widely divided by a field-glass. The two components are moving in opposite directions, and their apparent proximity is only accidental.

West of Corona (which at the time for which our map is drawn is nearly overhead) is Boötes, marked by the splendid orange star Arcturus. Below in the southwest is Virgo, with the very bright planet Jupiter outshining all her stars. Leo is low in the west, and Ursa Major well down in the northwest.

Ursa Minor and Draco are between the pole and the zenith. Cassiopeia and Cepheus are low in the northeast. Cygnus and Aquila occupy the Milky Way in the east, with Lyra above them, and Hercules still higher up. Capricornus is rising in the southeast, and Sagittarius farther to the southward. Scorpio shows splendidly in the southern sky, the whole curve of his tail being well visible, and Ophiuchus and Serpens are above.

NIGHT SKY: JUNE AND JULY

THE PLANETS.

Mercury is in conjunction with the Sun on the 3rd, and is invisible, except perhaps at the end of the month, when he sets about 8:15 P. M. and may be seen as an evening star. On the 29th he is close to the bright star Regulus, but both are low in the twilight. Venus is evening star in Leo and reaches her greatest elongation (or apparent distance from the Sun) on the 6th. She remains in sight until nearly 10 P. M. on the 1st, but, being farther southward nearer the Sun, sets about 9 o'clock at the end of the month. She appears telescopically as a fine moon at the beginning of the month and as a slender crescent at its close, and to the naked eye is near her greatest brilliancy.

Mars is in Aries, rising about midnight in the middle of the month. He is slowly moving eastward toward Saturn, and overtakes him in August.

Jupiter is in Virgo and adorns the evening sky. He is in quadrature with the Sun on the 29th, and is due south at 6 P. M.

Saturn is in Aries, a little east of Mars, and rises about an hour later.

Uranus is in opposition on the 20th, on which date he is in R. A. 19 h. 38 m. 21 s., declination 21° 30' 37" south, and is moving 10 s. west and 28" south per day. These data will enable those provided with setting circles on their telescopes to find him at once. Otherwise we may proceed as follows. A line from γ Sagittarii through a point half way between ζ and τ in the same constellation, carried as far again, points out a group of four small stars. Uranus is just half way between these and β Capricorni, in a very barren region. He appears as a star of the sixth magnitude, barely visible to the naked eye.

Neptune is in conjunction with the Sun on the 14th and is invisible throughout the month.

The Moon is nearest us on the 24th and farthest away on the 8th. She is in her first quarter at 4 A. M. on the 3rd, full at 7 A. M. on the 11th, in her last quarter at midnight on the 18th, and new at 3 P. M. on the 25th. Since new Moon comes so near perigee we may expect unusually high tides about this time, and also unusually low tides, the range of the tide being increased, but the average level of the sea remaining unchanged.

In her circuit of the heavens our satellite comes nearly in line with Jupiter on the 5th, Uranus on the 12th, Mars on the 19th, Saturn on the 20th, Neptune on the 24th, Mercury on the 27th, and Venus on the 28th. The conjunction with Jupiter is fairly close, but takes place after the Moon has set upon our part of the world.

Princeton University Observatory.

Peruvian Petroleum

EFFORTS are being made to develop more extensively the petroleum resources of Peru. The known deposits of oil occur in a very narrow strip of land between the foothills of the Andes and the shore of the Pacific, and much of this is flooded at high tide. Piles of railroad iron driven in the open ocean sand, which varies in depth from 5 to 30 feet, are used as foundations for the derricks. The shallowest of the driven wells is 1,000 feet in depth. There is very little gas, and the oil is very heavy, so that it can be put into tanks and shipped, and it is carried direct to the [illegible]

Curiosities of Science and Invention

Automobile Bridges in California

EXCEPT for a few streams which become flooded, and therefore impassable, during the rainy season, conditions in California are ideal for touring the year around. But until the Automobile Club of Southern California began its active agitation in the matter of good roads there was no effort to bridge these streams, and whole sections of the country were at times completely closed off from the rest of the world, the fords being impassable from floods and quicksands. Particularly was this the case in San Diego County at the crossing of the San Mateo and Santa Margarita rivers; and as visiting motorists in California all desired to go to San Diego by automobile, some means of transportation across these washes had to be devised. They had to be temporary, not only because of the expense of permanent bridges, but also because the club expected to succeed in its efforts to have permanent bridges built by the county. Accordingly, the club engineer devised the automobile bridge shown in the illustration. It is built of channel-iron 10 inches wide and 6 inches deep, braced together with iron strips, giving a spread of 56 inches over all, thus allowing the use of 6-inch tires and taking care of the average car.

The approaches to the bridge were built of wood, and the channel-iron troughs were raised upon concrete piers. One of these bridges was 84 feet long, not counting the approaches, and the other measured about 52 feet.

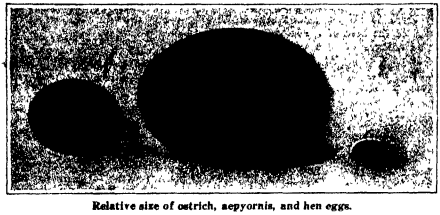
Odd method of launching a boat in China.

"Queen of the Forest"



"Monarch," a 96-foot fir

The "stone forest" of California.

The Largest Egg in the World

AN egg of the gigantic extinct bird aepyornis of South Madagascar is on exhibition at the Museum of Natural History, New York. The enormous size of the egg may be gleaned from the accompanying photographs. In one illustration a full grown pigeon is shown standing beside the huge egg, and in the other picture on the right is seen an ordinary hen egg; on the left is the egg of an ostrich. The aepyornis egg has a capacity of two gallons, or 150 times that of a hen's egg. The shell is ⅛ inch thick. Lengthwise it is 32 inches in circumference and it measures 26 inches around the middle. Though termed a fossil egg it is not petrified, but is in perfect condition, unbroken, and has a yellow color. The contents have turned into a fine dust which comes out, when handled, through a small natural perforation on one side. The aepyornis, like the moa of New Zealand, was exterminated by the hand of man. A few centuries ago it was quite abundant. Several incomplete fossil remains have been discovered, but no complete skeleton has ever yet been found. These show the bird was three-toed, of massive proportions and short winged. The Madagascar natives have for many years used the great egg shell for various household purposes. In fact, the first knowledge of these eggs became known when some Madagascar natives came to the Mauritius to buy rum, bringing the Aepyornis eggs with them to hold the liquor. Only three or four of these huge eggs have been brought into civilization. The present one is the most perfect as well as the largest known.

Relative size of ostrich, aepyornis, and hen eggs.

Aepyornis egg compared with a pigeon.

Launching a Boat in China

THE accompanying picture of a motor boat shows the ingenious method that the Chinese have for launching. The keel of the boat was laid on cross beams several feet above ground so that the planking could be easily put on. When it was ready for launching the pier shown in the picture was constructed of planks tied together and to the supporting posts by bamboo splits. Then bags made of coarse grass were filled with sand and stacked under the boat. The cross beams and other supports were knocked away, and then four men, two on each side of the boat, cut open the bags and as the sand poured out the boat settled slowly and comfortably down upon the pier. The boards underneath the three large cross beams were greased with coarse beef fat, and a half dozen men, by means of block and tackle, easily hauled it down the pier, where it was readily floated when the tide rose. Some of the bags of sand may be seen in the picture under the boat where it rests waiting for the incoming tide. By extending the pier the boat could have been launched directly into the water.

Home-made gasoline traction truck.

The "Stone Forest" of California

CALIFORNIA, among many other natural wonders, contains a "Stone Forest." This is located in Sonoma County, only a few miles from the little resort of Calistoga Springs. This "forest" consists of a great many petrified trees—all of which are prostrate.

In respect to the great number of petrified trees, and their immense size, the California "stone forest" surpasses that of Arizona. Strange to say, but very little is known about these wonderful Sonoma County petrifactions—so far as the general public is concerned. Many of these trees are of enormous size. The famous "Queen of the Forest" is a prehistoric redwood, about 80 feet long, and nearly 12 feet in diameter. It has been broken in several places, and these breaks are as clean as if cut off with a saw. A tree has grown up through one of the breaks and has attained quite a large size. Another giant tree known as the "Monarch" lies near by, which is almost 90 feet long and is without a break. This tree is a fir, and averages 10 feet in diameter. Not far away is another giant son of the forest—a redwood that is about 60 feet long and 9 feet in diameter. This tree is broken into many hundreds of pieces, yet it retains its shape almost perfectly. Scattered about for the area of several acres are many other pieces of petrifaction. So perfect has been the transmutation into stone, that the grain of the wood still remains very clear and the variety of the tree may be easily determined.

Home-made Gasoline Traction Truck

THE accompanying illustration shows an interesting home made traction truck designed at Shiloh, Ohio and utilized for sawing wood, grinding feed and pumping water. It is equipped with a 2½ horse-power two cycle gasoline motor provided with a throttling governor and weighs only about 200 pounds. It was built for portable power service, the equipment being arranged for moving the engine by its own power from place to place.

For pumping water the power is supplied by a pitman head on the rear of the truck, the pump being operated by a part of the same gearing that is used for driving the machine. The propelling chain is disconnected by a clutch when the engine of the tractor is used for pumping or similar service. The designer, A. E. Cross, is adding a rotary force pump mounted on the machine to be used for spraying trees and washing buggies. An equipment is also being provided for operating a power sheep shearing rig, so that a great variety of work can be accomplished by this unique outfit.

As may be observed in the accompanying engraving, the truck is fairly powerful for its weight and capable of climbing rough and steep grades.

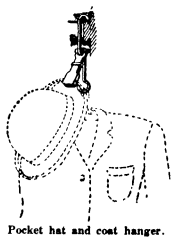
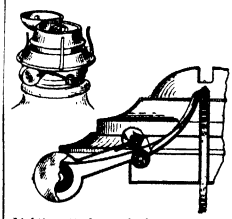
Oddities in Invention



Potato Pick-up.—An ingenious device for picking up potatoes which have been harvested by digging with the machine or by hand is shown in the accompanying engraving. It consists of a scoop attached to a handle and provided with a rake adapted to draw the potatoes into the scoop. The scoop comprises a mouthpiece and a basket. It is attached to the handle by means of a pair of links and the rake is attached to the scoop by

Potato pick-up.

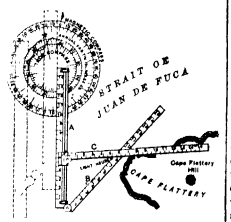
means of two links. When the device is supported by the handle it assumes the position shown by full lines in the drawing, but on pressing the handle forward the weight of the scoop is supported by the ground and the parts take the position shown by dotted lines in the drawing, from which it may be seen that the potatoes are drawn by the rake up the mouthpiece and into the basket.



Pocket Hat and Coat Hanger.—For the use of travelers and for those who may find it necessary to hang up a hat and coat in a place not provided with a fixed rack, a simple pocket device has been invented. This may be secured to the molding of a door or to any projecting part. The device consists of a prong bent over and provided with a pointed

Pocket hat and coat hanger.

end whereby the device may be attached to a support. Extending from the prong is a hook on which the coat may be hung. This hook is made in the form of a button hook, so that it may be used for buttoning shoes if desired. To hold the hat, a clasp hanger is provided consisting of a pair of spring arms which may be closed on the rim of a hat and be held by a loop or like retainer. When not in use the device may be folded into a small compass and carried in the vest pocket.



Lamp Igniter.—The lighting of kerosene lamps is usually quite a bother for the reason that the lamp chimney must be removed, and if this is hot it is necessary to wait for it to cool down in order to facilitate the lighting of the lamps. An inventor living in Colorado has devised a scheme by which the ignition may be accomplished by merely turning a thumb screw. An igniting strip is used, in the form of a roll, which is fed from a casing to the wick of the lamp. In the process of feeding the strip to the wick, it is dragged across a roughened surface that ignites the strip so that it is carried aflame to the wick.

Lighting attachment for kerosene lamps.

The accompanying drawing shows the mechanism quite clearly. The igniting strip is provided at intervals with protuberant ignitable heads. The scratching element which ignites these heads by friction bears against the upper surface of the strip immediately over the feed roll. The main body of the strip is incased in a heat-proof compartment so that there is no danger of setting it afire with the heat of the lamp. One of the advantages of this construction is that it may be used in connection with a lantern to ignite the wick in windy places where a match cannot conveniently be used.

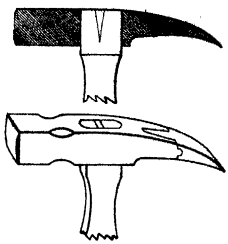
Instrument for Determining a Ship's Position in a Fog.—Hertzian waves travel 186,330 miles per second; sound travels 1,123 feet per second in air, at ordinary temperatures, and 4,593 feet per second in sea water. If a lighthouse should send out a sound signal simultaneously with a wireless telegraph signal it would be possible for a ship to determine its distance from the lighthouse during a fog by noting the time interval between the sound and wireless signals as they reach the ship. If after an interval the ship has moved a certain distance as measured by the log in the usual way, and its distance from the lighthouse is determined again, by noting the interval between the sound and wireless signals, we have the three sides

Instrument for determining a ship's position in a fog.

of a triangle, with the lighthouse at one point, and the two positions of the ship at the other two points. A simple instrument has been devised for laying off this triangle on a chart, so as to fix the position of the ship. It consists of a graduated scale *A* with two graduated arms, *B* and *C*, secured thereon, the arm *C* being capable of sliding motion along the scale. The instrument can be set so as to form a triangle with the three sides proportionate with the triangle determined by the signal observations. This may now be laid upon the chart with the graduated scale lying in the direction of the ship's course as indicated at *A*, and the junctures of the two arms *B* and *C* at the lighthouse, when the position of the ship will appear at the junction of arm *C* and the scale *A*.

Shoe Button Remover.—A simple device has been invented which may be applied to an ordinary pair of shears to facilitate the removal of shoe buttons. This device, as shown in the accompany-

Shoe-button remover.



ing illustration, consists of an extra blade that is forked and slightly bowed. It is attached to the shears by means of a pivot bolt and a pin that serves to make the connection rigid. In use the forked blade is slipped under the button, serving to draw it away from the material so that the blades on the shears are in the right position to sever the threads without danger of cutting the material and with no liability of coming in contact with the metal shank of the button. When it is desired to sharpen the shears the attachment may readily be removed.

Combined Mop Head and Wringer.—The task of wringing out a mop is so disagreeable that many devices have been invented for performing the operation mechanically. Instead of providing a separate wringer to be used with the mop, an inventor has recently hit upon the idea of constructing the mop in such a way that it constitutes a wringer as well. The accompanying illustration shows the mop in section. As may be seen it is composed of two principal parts, one a central shaft with a collar secured thereon, and the other a sleeve mounted so that it can turn on the shaft. The mop proper consists of yarn looped from the sleeve to the collar in such a way as to form a double walled cylinder. The yarn is applied in a continuous length, being held in place by means of wire which encircles the sleeve in one case, and the collar in the other, being firmly clamped thereto. The mop may be used in the ordinary way, and when it is desired to wring it the sleeve is held in one hand and the handle of the mop is rotated therein, causing the yarn to be twisted and wrung out thoroughly.

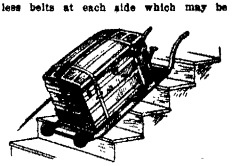
Combined wringer and mop.

Improved Bricklayer's Hammer.—That part of the bricklayer's hammer with which the bricks are chipped off, and which is known as the peen of the hammer, is liable to wear out before the rest of the hammer does. For this reason an inventor has devised a hammer in which the peen is made readily removable. The way in which this is done is clearly shown in the illustration, a locking joint being provided between the peen and the hammer which will stand the thrust when the peen is in use. The peen may be made of high carbon steel so that it will wear for a great length of time, while the rest of the tool may

Hammer with detachable peen.

be made of an inexpensive low carbon steel. When the peen wears out it may be detached quickly and replaced with a new peen.

Adjustable File Handle.—The accompanying engraving illustrates a handle for files which is adaptable to files of different sizes and may be readily applied or removed. It holds the file by the tang in such a way as not to project



Adjustable file handle.

below the operating surface of the file. This permits of using the file perfectly flat, which in the majority of cases is of great advantage. The clamp by which the file is attached to the handle consists of two jaws that can be locked and tightened upon the tang of the file by means of a wedge. This in turn is held in place by means of a set screw.

Hand Truck for Stairways.—In order to facilitate the transporting of trunks up and down stairways, as well as upon level surfaces, a hand truck has been provided which in addition to the usual wheels in front, is provided with endless belts at each side which may be

Hand truck for stairways.

used as running surfaces in the manner shown in the illustration. The belts are supported at frequent intervals by rollers and bearing blocks. When moving the trunk up or down a stairway, the wheels clear the steps, but the belts

against the sinking of the treads. Felts prevent any possible marring injury to the woodwork and they may be employed, as well, on level surfaces that are not carpeted if it is desired to prevent marring the floor.

Edison Giant Roll Patents Sustained

AN important decision has just been handed down by Judge Hazel in the United States Circuit Court of the Western District of New York in a suit against the Allis-Chalmers Company and two of its customers, the Empire Limestone Company and the Casparis Company, on Edison patents Nos. 672,616 and 672,617, granted April 23rd, 1901, on the so-called Giant Rolls. These rolls are referred to in the recent book, "Edison: His Life and Inventions, by Frank L. Dyer and T. Commerford Martin":

"No such departure was as radical as that of the method of crushing the ore. Existing machinery for this purpose had been designed on the basis of mining methods then in vogue, by which the rock was thoroughly shattered by means of high explosives and reduced to pieces of one hundred pounds or less. These pieces were then crushed by power directly applied. If a concentrating mill, planned to treat five or six thousand tons per day, were to be operated on this basis the investment in crushers and the supply of power would be enormous, to say nothing of the risk of frequent breakdowns by reason of multiplicity of machinery and parts. From a consideration of these facts, and with his usual tendency to upset traditional observances, Edison conceived the bold idea of constructing gigantic rolls which, by the force of momentum, would be capable of crushing individual rocks of vastly greater size than ever before attempted. . . . He proposed to eliminate the slow and expensive method of breaking large boulders manually and to substitute therefor momentum and kinetic energy applied through the medium of massive machinery which, in a few seconds, would break into small pieces a rock as big as an ordinary cottage piano and weighing as much as six tons. Engineers to whom Edison communicated his ideas were unanimous in declaring the thing an impossibility; that it was like driving two express trains into each other at full speed to crack a great rock placed between them; that no practical machinery could be built to stand the terrific impact and strains. Edison's convictions were strong, however, and he persisted."

Judge Hazel, in referring to the patents under consideration and in setting forth a judicial review of Edison's accomplishment, said:

"Mr Edison's object was to devise a method by which massive rock or boulder when taken from their bed could be instantaneously crushed or broken into pieces at the least possible expense by the blows of large projections on the rollers and thus to eliminate the hand sledging or blasting of the prior art. To accomplish his object it was necessary that the rollers correspond in weight and strength to the size of the material to be broken up. He believed it possible to use the energy and force generated by the inertia of revolving objects. The problem was how to apply such energy to assist in the crushing operation. Kinetic energy is the term by which such force and power is technically known. The skilled engineer knew that a heavy rotating object contained stored power and energy component with it, and in the adaptation of such force and power for breaking and crushing large rock, it will be comprehended that if such energy could be practically used an achievement of great economic value and benefit in this art would result. It was necessary to design and construct machinery and rollers of a peculiar kind together with facilities for placing and using them in accordance with the methods operated and specified in the patents in suit. The patentee surmounted all obstacles and the record shows there were many. He was the first to evolve a crusher by which kinetic energy became a potential factor in the method of crushing and breaking rock by blows from the knobs on rollers. It scarcely can be doubted that his inventions are meritorious and involve in their organization and perfection patentable skill of a high order."

The court then refers to the claims of the two patents, one covering broadly the method involved in crushing rock by kinetic energy and the other relating to the apparatus employing the two massive rolls which are so driven as to permit the crushing and breaking to take place. It was urged in defense of the suit that crushing rolls of much smaller size had been made, assembled, geared together, and that no invention would be required to increase the size and weight of such rolls and to dispense with the gear so as to permit the rolls to operate independently. Concerning this defense, Judge Hazel said:

"A number of patents for crushers having rollers are claimed by defendants to anticipate and limit the claims in controversy, but such patents are inapplicable. To bring together and adapt in dimensions, iron rollers of such large proportions inclosed in a frame and providing means for periodically storing kinetic energy and periodically expending it as described in the specifications, was invention of the highest merit. It was not simply a question of changing the proportion, size or shape of the rolls. New and novel additions in crushing apparatus were made. The prior crushing or pressing rolls contained no helpful suggestions to the patentee as to the manner of using kinetic energy to instantaneously fracture heavy rock. Although the prior art shows crushing rolls with irregular surfaces, yet such rolls were geared together and were not driven by a belt in opposite directions. They were incapable of delivering blows to powerful rock masses. Indeed there is a total absence in the prior art of the use of kinetic energy to secure the hammering action necessary to break such heavy material as contemplated by Edison's invention. . . . In the prior art there is not disclosed any method or apparatus for breaking rock by the medium of crushing rolls which are provided with knobs or projections and are driven by belting. They were provided in most instances with teeth or projections and the rolls which were geared together and their function was to compress, pinch or pick the material to separate the particles. The driving agent apparently performed the work of crushing the material while in the patents under consideration there is a distinct departure, the material being wholly crushed or broken by the energy of the knobs on the rolls. Although some of the separate elements of the claims in controversy were old and are found in the prior apparatuses, yet such old elements had never before been assembled or combined to use power stored in the rolls to break or crush rock nor prior to the inventions in suit had such rock been broken or crushed by hammer blows from projections on the rolls driven by belt and rotating in opposite direction. It is not enough to select separate elements from different devices and then without making any patentable change or improvement insist, as do the defendants, that the patented structure might have been similiarly constructed. The claims are entitled to such a fair construction as will preserve to the inventor the fruits of his discovery."

The defendants structure was held to be an infringement. On this subject the court said:

"To summarize, the defendants' rolls in operation are substantially the same as those of complainant, having a like capacity for crushing rock; they use the kinetic energy to break the material periodically dumped upon the rolls and their operations perform the functions of the patents in suit and achieve the same result. The method patents describe the mode of treatment of the rock by which it may be shattered and the series of steps to be taken in the transforming process.

"The combination of elements by which the splendid results of breaking rock by blows due to the use of kinetic energy were attained undoubtedly involves the exercise of invention as distinguished from mechanical skill. The prior art neither suggests the patentee's method nor the apparatus by which the work could be done."

How I Invented the Air Brake—III*

By George Westinghouse

THE next event of importance was the application of the brakes in November, 1869, to a longer train of ten cars upon the Pennsylvania Railroad, which was taken to Philadelphia for the purpose of demonstrating to the directors of that railway the success of the apparatus. I may say at this point that the Pennsylvania Railroad had been using for some years a chain brake similar to the one applied by Mr. Ambler, but had found that its use was limited to short trains and that it was not a satisfactory contrivance for the purpose intended. There were invited to witness these trials in Philadelphia a large number of railway people, and the papers gave extended notices of the tests made, which brought to the train on the next day Mr. George L. Dunlop, the general superintendent of the Chicago & Northwestern Railway, who was desirous of having the whole apparatus fully explained to him. The result of this inspection of the air brake apparatus was an invitation to make a demonstration upon his railway in Chicago, and he offered, if the Pennsylvania Railroad would send a train for the purpose, to invite the leading railway people and members of the press of that vicinity. The apparatus was then transferred to a train consisting of a new locomotive and six new cars, and this train was run to Chicago over the Fort Wayne Railroad, and a number of tests were immediately afterward made upon the tracks of the Chicago & Northwestern Railway, evidently to the entire satisfaction of those present. From Chicago, the train proceeded to Indianapolis, where other tests were made, and then back to Pittsburg.

The outcome of these demonstrations was immediate orders for equipment for the Michigan Central and the Chicago & Northwestern, and shortly after for the Union Pacific Railway in the West, and for the Old Colony and the Boston & Providence roads in the East.

I refer to these details to illustrate the readiness with which railway officials took up this invention and the comparative ease with which the required orders were secured, and because it has been often stated that the trials and tribulations in the introduction of the brake were of the severest nature.

Works were built in Pittsburg for the manufacture of the apparatus and were fitted with the best tools obtainable. Standards were adopted and adhered to in the parts of the apparatus which required uniformity in construction in order to insure interchange of the rolling stock so fitted upon various roads. I think I am safe in saying that the course pursued in the manufacture and introduction of the brake had a more important bearing than anything else in deciding the railway master mechanics and master car builders a few years later to take up the question of the standardization of various parts of cars in order that repairs could be more conveniently made.

It soon developed that it took considerable time to apply the brakes with full force and a longer time to release them, and that in the event of a break-in-two of a train (a frequent occurrence in those days) the rear section would be uncontrolled, and when this occurred upon an ascending gradient, the rear detached section might run away, with disastrous results. To overcome this difficulty a new development was necessary, the outcome of which has since been known as the automatic air brake.

In the automatic air brake equipment there were the same air-pump, reservoir, train pipe and brake cylinder, but in addition to these there were two important features added to the tender and each car equipment, the first, an auxiliary reservoir, and the second, a triple valve or device interposed between the brake pipe, brake cylinder and auxiliary reservoir. This triple valve was so constructed that when air was admitted to the train pipe, an opening was established between the train pipe and the auxiliary reservoir whereby the train pipe and reservoir were filled with air under pressure. The valve also opened a passage from the brake cylinder to the atmosphere. This was the normal condition of the apparatus when the brakes were off. To apply the brakes, the engineer discharged a portion of the air from the train pipe, whereupon the triple valve closed the connection between the brake pipe and the reservoir and between the brake cylinder and the atmosphere, and then opened a passage from the auxiliary reservoir to the brake cylinder, the piston of which was moved outwardly by the air from the auxiliary reservoir so as to apply the brakes. The restoration of the pressure within the brake pipe released the brakes and recharged the reservoir. This development occurred during 1872 and 1873.

The automatic brake was at that time supposed to be instantaneous in its action in applying the brakes, and almost instantaneous in releasing them. In the event of the escape of air from the train pipe by its rupture or by the separation of the train, the air stored in the auxiliary reservoirs instantly and automatically applied the brakes to all parts of the train and they could only be released by either repairing the damage and restoring the pressure, or by means of special release valves operated by the train men.

The automatic brake having proved itself vastly superior to the plain or straight air brake first described, it soon became a standard, but during the transition period an automatic brake was easily converted into a plain brake by a manually operated special valve arranged in the casing of the triple valve.

The gradual increase in the length of freight trains and the numerous accidents due to lack of brake control early suggested that automatic air brakes should be made a part of the equipment of all freight trains, and to determine the practicability of the automatic brake for this purpose a train of fifty cars was fitted in the early eighties and taken over the Alleghenies on the Pennsylvania Railroad, and the tests made demonstrated that such a train could be controlled on the heaviest gradients by this means.

In 1885 the Master Car Builders appointed a committee to report upon the feasibility of the application of brakes to freight trains, and this committee inaugurated what are now known as the Burlington (Iowa) brake trials, made in 1886 and 1887. There were presented two trains fitted with air brakes, one fitted with a vacuum brake and one with the brake operated by means of attachments to the drawbars similar to the conception first referred to. Each of these trains had fifty cars. These tests proved the inadequacy of the type of automatic air brake then presented by the Westinghouse Air Brake Company, as well as the inadequacy of all the other brakes then tested.

It becoming apparent that the lack of success at Burlington was due to the comparatively slow application of the brakes upon the rear portion of the train, the effect of which was to cause most serious shocks almost like collisions, a new development was imperatively needed in order to insure the successful handling of freight trains of fifty cars.

As a part of the automatic air brake passenger equipment, I had developed in the seventies a system of train signaling involving the use of a second train pipe, which is now in general use upon all of the railways. This signalling apparatus had a sensitive valve device connected to a small reservoir upon the locomotive, and these were so arranged that when compressed air was admitted through a small opening into the signalling pipe, both the pipe and reservoir were charged to a low pressure (at the present time to forty-five pounds). By opening a valve at any point in the train to permit a small quantity of air to escape from the signal pipe, the delicate valve referred to was caused to move so as to admit air from its auxiliary reservoir to blow a whistle located in the cab of the locomotive. It was found upon experimentation that when the valve in any car remote from the engine was quickly opened and closed as many as five times, the whistle would be blown an equal number of times, the first time being after the last escape of air, that is to say, there were set in motion five distinct waves of air, each capable of doing work.

During these developments it was found that the waves of air within the brake pipe traveled as rapidly as sound, i. e., about 1,100 feet a second.

(To be continued.)

* From Presidential Address presented at the Annual Meeting of the American Society of Mechanical Engineers.

Legal Notes

A Bad Patent Bill.—Representative Oldfield member of Congress from Arkansas, and chairman of the House Committee on Patents, introduced on May 5th, 1911 a bill (H R 8,776) to amend Section 4,886 R S to include provisions for compulsory licensing upon the order of the Commissioner of Patents and for the determination of the patent if such order be made and not complied with within a time limited The bill also contains a Section 2 which is entirely independent of the compulsory license feature, and reads as follows

"Sec 2 That all patents of improvement of any new and useful art, machine manufacture or composition of matter shall in no event operate to extend the life of the original patent, but such patent on such improvement or improvements shall expire on the date of the expiration of the original patent "

There is little prospect of any patent legislation being effected at the present session of Congress, and doubtless full hearings will be accorded by the Patent Committee on the foregoing bill, before any report is made thereon to Congress It requires but a casual reading of the bill to appreciate how detrimental it would be to the inventive public as well as to the public generally in stifling invention limiting the opportunity of the inventor to properly control and profit by his invention and retarding the great commercial and other progress which necessarily results from the development of the arts by the exercise of invention under the fostering influences of the patent laws of to-day

This idea of compulsory license is not a new one to Representative Oldfield, who introduced the new bill, for he was on the Patent Committee of the Sixty-first Congress, and he doubtless remembers the able arguments in opposition to the license proposition advanced by learned counsel at the hearings in the winter and spring of 1910, particularly that of Mr Frederick P Fish of Boston On the constitutional phase of the question, Mr Fish speaks with great force, saying

"The Constitution of the United States, with wonderful foresight, as I look at it, says that Congress shall have the power to reward the inventor and to promote the useful arts by giving him the exclusive right for a limited time What does that mean? It means what it says, the power to give him an exclusive right, not the power to give him some other kind of right, and the courts have so construed it I question the constitutional power of Congress to interfere in this matter It can make no difference whether you deal with the inventor or the assignee If you give the inventor the exclusive right, that is one of the things he sells to the assignee If the law is changed so that he is obliged to say 'I cannot give you the exclusive right, of course, because Congress has passed a law saying that at any time or at some time certain things may happen to take it away from you'"

Again, on this point, Mr Fish said, "In view of the invariable construction that has been given to the Constitution down to the present day, and in view of the conditions of the English law at the time our Constitution was established I think the Court ought to say— I don't know what they would say— that when the Constitution said 'exclusive right' it meant that and nothing else That is, the exclusive right to make, sell, and use, as the statute states it, and the courts have so construed it, because the Constitution required it But that is only my view, and I hope that it will never get to the point where the constitutional question will have to be raised."

As to the practical effect of compulsory licenses Mr Fish said:

"Compulsory license would be fatal The whole patent system of the United States would be demoralized. The industries of the United States have a hard enough time ahead of them for several years to come and if we lose the merit of our patent system, I don't know what would happen. The whole stimulus now existing for the development and improvement of industries would in my judgment be shaken to the foundation if there should be any interference with that particular phase of the situation by which for a short time—so short, as I say, that half of it is wasted in the case of nearly every good patent—a patentee has the absolute control of his invention"

Notes for Inventors

A Machine for Selling Luncheons.—The popularity of quick lunches attracts attention to a patent for a dispensing machine, patent No 994,717, to Frederick O Bullis of Rochester whose machine automatically delivers a portion of food and provides for automatically measuring a portion of condiment as the food is delivered, while the delivery of the condiment is under the control of the operator

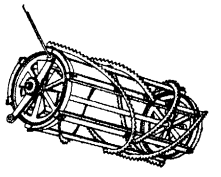
Pipe Holder.—Pipe smokers will find some comfort in an attachment for smokers' pipes which Howard Elliott of Washington, D C, presents in a patent No 994,913 It is a small, neat affair, having a clamp by which it may be spring-held on the stem of a pipe with a projecting plate forming a rest to support the pipe in an upright position on a table or stand, the projecting pla also forming a means for hanging the pipe up on a hook or nail when not in use

Enriching Coffee.—To improve the quality, soften the flavor and enrich coffee is the stated object of a patent, No 994,785, to Ellis M Potter of New York city He seeks to accomplish these objects by mixing green chicory root with the green coffee bean or berry and roasting the mixture, the coffee being subsequently separated from the chicory

Driving Devices for Gas Engine Fans.—In patent No 994,764, assigned to Gilbert J Loomis of Erie, Pa., the theory is applied that when the engine is running with a light load but with a high speed, the cylinder radiator or condenser is not so highly heated as when the engine is running slower. With a higher load, the invention provides means for automatically varying the relative speeds of the fan and engine so that the fan may be given a maximum velocity with the low speed of the engine and this velocity is so varied as the engine is speeded up as to keep the velocity of the fan within the limits of safety

New Explosive.—The E I Du Pont de Nemours Powder Co is the assignee of the patents 994,841 and 994,842 for inventions of Harrold Hibbert of Wilmington Del, in explosives including butylene glycol nitrate alone and in connection with nitrates and nitro compounds

A Westinghouse Patent.—George Westinghouse of Pittsburg has just patented No 994,810, cooling and ventilating means for electrical apparatus in which a system of fluid passages having inlet and delivery ports are combined with rotary and stationary parts and the velocity of flow of fluid through the passages is affected by the withdrawal of the fluid from the delivery ports



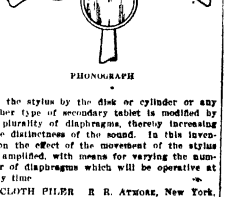
A Pocket Ink-stick.—Fountain pens are widely used and Harry N. DeLanoy of Nelsonville, N Y, has patented No 994,724, an ink stick or cartridge which can be conveniently carried in the pocket and cleanly handled and will render the use of a filler unnecessary. The cartridge is in the form of a porous splint whose surface film is of a coloring substance soluble in water and is formed of a dry powder adhering to the surface of the splint.

RECENTLY PATENTED INVENTIONS.

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Of Interest to Farmers.

MANURE SPREADER.—George W. Barnard, Economy, Ind. This invention relates to manure spreaders in which the material is distributed from a wagon by means of a distributing cylinder or beater. The cylinder is shown in perspective in the engraving The purpose is to provide a distributing cylinder which will be simple in construction and



MANURE SPREADER.

reliable in operation, the distributing cylinder being so constructed that it will not only separate and practically pulverize the manure, but will scatter the same broadcast over a greater area than that occupied by the machine Patents in this case are pending and to be taken out in Canada, Great Britain, Germany and other foreign countries.

TOOL W J Strealy, Lewisburg, W. Va An object in this invention is to provide a device which ordinarily can be carried by inserting the handle thereof on the pole of the reaper or mower, and which, when it is desired to use the same, can be readily clamped onto the wheel of the machine and utilised to great advantage

Of General Interest.

PHONOGRAPH SEPTIMUS T. E. White, 308 W 3rd St., Oklahoma, Okla., and John E White, New York, N Y A fragmentary plan view is illustrated in the engraving, in which auxiliary sounding boxes are shown connected in multiple with the primary sounding box The invention relates to an improvement whereby the effect of the vibrations imparted

PHONOGRAPH

to the stylus by the disk or cylinder or any other type of secondary tablet is modified by a plurality of diaphragms, thereby increasing the distinctness of the sound. In this invention the effect of the movement of the stylus is amplified, with means for varying the number of diaphragms which will be operative at any time

CLOTH PILER R R. Athore, New York. N Y The aim in this invention is to provide, in connection with a table and a reciprocating carriage and track for supporting the same for the purpose of laying the fabric on said table in superposed folds, a guide or set of guides for properly positioning the fabric as it is being laid

LOCK BEAM TUBE.—P. H. Frim., New York, N Y This improvement provides means for interlocking the various layers of metal wherefrom the completed tube is constructed in a form wherein the joined ends of each layer are prevented from spreading by the body structure of the other layer; and provides a tube constructed of a series of layers arranged to form a continuous wall having an even thickness.

IRRIGATING SYSTEM.—J. T. Donahoo, Edgar, Neb. An object here is to provide a system which may be successfully employed in those valleys in which there is a stream of water at whose level the land of the valley is more or less wet Another is to provide a system in which lands at some distance from the stream may be irrigated without the necessity of making ditches or canals leading from the stream itself.

Miscellaneous Devices.

SAW GUIDE.—C. Hammond, Mt. Pleasant, Colo. This invention relates to saw guides and is adapted to be quickly set and adjusted to hold a saw steadily and accurately in position as it cuts into the log, so that the cut can be commenced at all times. The guide is made of a support for clamping it to the tree, and a series of adjustably connected supports, and a saw guide member mounted on one of the supports and adjustable to slide in the guide.

WRENCH.—Lorenzo E. E. Schuster, Minot, N. D. This invention relates to wrenches, and the more particular purpose is to provide a tool of this general character suitable

WRENCH.

use either alone as a hand instrument or in combination with a rotary brace. More particularly stated the invention shows in the engraving provides a wrench having a two-part shank adapted to be bent and used as a handle or to be straightened and put into a brace, the tool further comprising various portions whereby it is adapted so be used as an alligator wrench, a monkey wrench, or a socket wrench.

CLAMP.—S Adell, Orange, Mass. In this case the invention provides a clamp for reliably clamping articles of various dimensions and proportions. Use is made of handled clamping screws, having clamping bars operatively mounted thereon, with means in one of the bars for screw threadedly engaging the clamping screws and means in the other clamping bar for preventing the said bar from sliding longitudinally on one of the clamping screws.

Household Utilities.

WINDOW CLEANER—John W. Gibbons, 2725 Jackson St., Baker City, Ore. The invention illustrated by the engraving relates to a device for cleaning windows or the like, which

WINDOW CLEANER.

is in the form of a flexible pneumatic wiper that is adapted to be rotated by a suitable source of power at any suitable angle An object is to provide a cleaner with a buffer, and means for tilting the buffer to various angles with its support; to provide a flexible pneumatic buffer with means for tilting the same from the source of power, and with means for automatically disconnecting the tilting means from the source of power when a predetermined position of the buffer has been reached; and to provide a cleaner which may be adjusted at to its length within friendly reach of the source of power.

Classified Advertisements

Advertising in this column is 25 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

BUSINESS OPPORTUNITIES

Cement dealer buys business in bronze marine goods; wants to procure patents or rights to patents which is mail-order, the full line of brass, steel and copper foundry, machine shop and polishing room. Rear New York. Address Inquiry, Box 773, Scientific American, 361 B'way, New York.

Well known manufacturer, with selling offices throughout the United States, operating an extensive plant, will arrange to manufacture and create a market for patented inventions of small staple articles of general use in small order business preferred. Article must sell at moderate price. Chemical, brass, metal spinning, tubing, woodworking and finishing, surface and silver plating facilities. Will also buy quantity of article with local dealers or salespeople if purchase price makes it worth while. Address Box 1, for full details. Investigation is free and confidential.

PATENTS FOR SALE

To sell, or on other agreements, Sheffels Patent No 1000, new principle of increasing speed of boats or vessels and keeping to same without steam. Could offer services and make additional improvements. Address, Joseph Sheffels, Lower Mill, Thornton, near Bradford, Yorkshire, England

WANTED.

AGENTS—PENCIL CIGAR LIGHTER, latest invention. Sells itself. Pictures impossible. Samples will not interest only pocketed. Mr. Mosby Manufacturing Co., Dept. C, Chicago.

MISCELLANEOUS.

THE MOST POWERFUL LIGHT in the world. Hall-Scheim, Germany. Four cents of this and many other light-novelties sent postpaid on receipt of 10c. We are specialists in lighting devices. Catalog free anywhere, or send 10 cents for sample. Agents wanted. We will send 25 assorted samples also catalog. Lightheese Mimeon. Dept. "E A." 11 Lincoln Sq., Belfast, Ireland.

CIVIL SERVICE EXAMINATIONS open the way to good Government positions. I can coach you by mail in small sum. Full particulars free. Write at once for Booklet 14 Mert Hopkins, Washington, D. C.

$3 INDEPENDENT—Most Money Making Mail Order Business at Home. New York. Everything furnished. Outfit free. Opportunity of lifetime. Don't lose time. B. A. Miller Co., Box 32, Madison, Miss.

LISTS OF MANUFACTURERS.

CORRECT LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at very reasonable rates. Information obtained by cablegram or airmail. Address Munn & Co., Inc., Law Department, 361 B'way, New York.

INQUIRY COLUMN

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you can supply any of these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for the service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

Inquiry No. 6966.—Wanted, addresses of owners of [illegible] machine for making [illegible] per hour.

Inquiry No. 6941.—Wanted, addresses of owners of [illegible] machine for [illegible] for [illegible] of [illegible].

Inquiry No. 6943.—Wanted, address of manufacturers of [illegible] sweepers, and driers suitable for [illegible].

Inquiry No. 6944.—Wanted, addresses of parties who manufacture or use [illegible] for [illegible].

Inquiry No. 6945.—Wanted, to buy a [illegible] machine.

Inquiry No. 6946.—Wanted, the name and address of a [illegible] who can [illegible] a patent rolling machine which will [illegible] and [illegible] at the same time.

NEW BOOKS, ETC.

DICTIONARY OF AVIATION. By Robert Morris Pierce. New York: The Baker & Taylor Company, 1911. 287 pp. Price, $1.40 net.

In his preface Mr. Pierce tells us that it has been his attempt "to produce a word book for the use of persons interested in aviation from any of the various points of view from which it may be contemplated, or from any of the starting points from which it may be pursued." That he has succeeded in this attempt, even the most cursory examination of the book must prove. In the effort to be complete we find many a curious compound which has unnecessarily swelled the volume of words. Thus we find such unnecessary combinations as "aeroplane-accident," "aeroplane-experiment," "aeroplane-flight," "aeroplane-owner," "aeroplane-race," "aeroplane-term," "aeroplane-tower," and "aeroplane-work." Compounds such as these may be produced almost by the hundred. Perhaps that explains why this dictionary contains no fewer than 4,276 title words and phrases. In the definition of a helicopter, we are told that such machines depend "for lifting or sustaining power upon vertical screws or rotating air foils," where evidently a horizontal screw is meant.

THE NEW INTERNATIONAL YEAR BOOK. New York: Dodd, Mead & Co., 1911. 837 pp.

Among the noteworthy features of this year's International Year Book, which may well be regarded as an annual encyclopedia, are politics, current history, and biography. Subjects such as the referendum and initiative, conservation, municipal government, banks and banking, strikes and lockouts, arbitration, in other words, subjects which have occupied considerable space in the public press during the past year, are treated with commendable fullness. On the other hand, we find the division or aeronautics rather one-sided. The developments in aviation are summarised well, considering the limitations of space, but the development of the dirigible, which has been truly remarkable, is limited to a description of Wellman's "America," the Zeppelin airships, the Willows dirigible, and the "Clement Bayard II," notwithstanding the fact that the Parseval has made wonderful records, and that almost every military power of Europe has for two years past been engaged in the building of dirigibles. The article on astronomy is good. As is natural, considerable space is devoted to Halley's comet. It is no longer seriously thought by astronomers that light pressure is the sole cause of the phenomena of the comet's tail. More space should have been devoted to the discussion of new stars. The topics under the head of physical chemistry seem to have been rather arbitrarily selected. Considerable space is devoted to radium paper and fiber, artificial rubber, permutite filtering, but no space at all to the industrial application of the new coal-tar dyes, perfumes, and the like. Achievements in electro-chemistry and electro-metallurgy, in which new events may be recorded almost from month to month, find no place whatever in the Year Book, though some curious oversight. Indeed, in science and engineering the Year Book seems to be weakest, and it is just here where it should be at least as strong as in other portions. This criticism made we should not militate too seriously against the book for there can be no doubt that as a piece of painstaking compilation of happenings during the past year it will prove a valuable reference book.

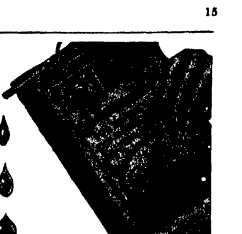
A CONCISE HISTORY OF CHEMISTRY By T. P. Hilditch. New York: D. Van Nostrand Company, 1911. 268 pp. Price, $1.25.

Considerable interest is being manifested at the present time in the history of arts and science. It seems indeed as if no rational person, living in this age of the most remarkable scientific achievements, could remain in perfect indifference, never giving a thought to the inquiry after the origin and growth of this wonderful element of our civilization. To the student of science, some familiarity with the history of his subject is indispensable for a thoroughly intelligent grasp of his work. It is true that perhaps the best mode of acquiring this familiarity is through the consultation of the original publications. The process of thus imbibing historical knowledge is, however, slow, and for the most part falls into the period of a man's life work rather than into his college years. For reading to be carried on concurrently with the younger student's regular work, such a hand book as the one before us is eminently desirable. The author gives a brief but very excellent survey of the principal phases of the history of chemistry. The text is divided into eleven chapters, under the following headings: I. The Evolution of the Science. II. The Chemical History of Fire, Air, and Water. III. The Ultimate Constitution of Matter. IV. Inorganic Compounds and the Laws of Chemical Combination. V. Notes on the History of the Elements and their Chief Compounds. VI. The History of Organic Chemistry. VII. Compounds and Reactions in Organic Chemistry. VIII. The Chemistry of Plant and Animal Life. IX. The Application of Chemistry to Manufactures. X. The History of Physical Chemistry. XI. The Progress of Experimental Method. There are two appendices, the first giving a biographical index of the great chemists, a brief résumé of the man's most important contributions to science being given under each name. The second appendix is a tabular summary, in chronological order, of chemical events of out standing interest. The book is one of more than ordinary merit.

MODERN GUNS AND GUNNERY. A Practical Manual for Officers of the Horse, Field, and Mountain Artillery. By Brevet Colonel H. A. Bethell, Royal Field Artillery, Woolwich. 1910. J. J. Cattermole, Wellington Street, 1910

This comprehensive and admirable work has been written for the use of officers who may be deterred from a study of some other text books because of the real or imaginary terrors of the mathematical demonstrations with which their pages are apt to bristle. While the designer of guns, carriages, and ammunition must have an exact mathematical knowledge of the science of gunnery, the officer who uses the gun need have no more than a clear understanding of the principles of gunnery to enable him to apply these principles in handling the guns. This work is intended first as an easily understood manual for those whose whole duty leaves them no time to master the difficult science of gunnery, and secondly it is intended as an introduction to the study of more advanced books. The last edition, written in 1904, has been thoroughly rewritten in producing the present work. The theoretical portion has been altered, the ballistic tables made more perfect, and some of the older theories have been modified by recent experience. The book is divided into four parts, consisting of "Theoretical Gunnery", "Principles of Construction of Guns, Carriages, and Amunition", "Practical Gunnery", "Sighting Quick-firing Equipments", and "Gunnery Calculations". It is sufficient to say that the author has succeeded thoroughly in his aim to be comprehensive and clearly understood. The work is abundantly and judiciously illustrated, and is one of the best of its kind that it has been our pleasure to review.

THE SEVEN FOLLIES OF SCIENCE. By John Phin. New York: D. Van Nostrand Company, 1911. 231 pp., 34 illustrations. Price, $1.25.



This is the second edition of a book which has deservedly found favor. The follies enumerated are: Squaring the circle, the Duplication of the Cube, the Trisection of the Angle, Perpetual motion, the Alchemical transmutation of metals, the Fixation of mercury, the Universal medicine and the elixir of life. These seven follies constituted practically all of the first edition of this book. In this second edition will be found discussions of perpetual or ever-burning lamps, the alkahest or universal solvent, palingenesy, the powder of sympathy, besides a number of paradoxes, illusions and marvels which should hardly find a place in this book, and which include the Fourth Dimension, How a space may be apparently enlarged by merely changing its shape. Can a man lift himself by the straps of his boots? How a spider lifted a snake. How the shadow may be made to move backward on the sundial. How a watch may be used as a compass, etc. We rather wonder, too, why curious arithmetical problems should have been included in this book. More appropriate is the discussion of such questions as the following: That most great discoveries are made by accident. That the idea of the steam engine was suggested by a teakettle. That whetstones are oiled to lessen friction. That lightning never strikes twice in the same place. That the first fire came from branches of trees moved by the wind. That volcanoes are burning mountains. That the force of dynamite is always exerted downward. That steam can be seen, etc.

THE OPEN BOOK OF NATURE. An Introduction to Nature Study. By the Rev. Charles A. Hall. New York: The Macmillan Company, 1911. 8vo., 288 pp., Illustrated. Price, $1.75 net.

Nature with an English background is here pictured in such a way that young readers will be led to identify the commoner forms of life, to name the birds and to know their eggs, to name the wild flowers and learn their well-loved nooks. There is a glossary which will prove very useful.

HOW TO USE THE ELECTRIC LIGHT WITH INCREASED ECONOMY AND EFFICIENCY. Including a Chapter on Electric Heating. By Frederick H. Taylor. London: Percival Marshall & Co. 76 pp. Price, 25 cents.

A simple instruction book for householders, shop-keepers, and factory owners. It contains enough good hints to make its perusal by the consumer of electricity well worth while, but it must be read with the understanding that it is written from the standpoint of the electrical industry and with reference to English conditions, which in many instances differ greatly from those of America.

Nothing is so vital to the life of an automobile as a proper lubricant.

The following elements are essential:

Proper Adhesiveness:

Adhesiveness in lubricating oil is the property of clinging to metallic surfaces. **Polarine has the correct adhesiveness for motor car use.**

Proper Cohesiveness:

Cohesiveness in an oil is its property of clinging together to maintain a proper film between wearing surfaces. Two oils may maintain this film equally well at one temperature, yet materially differ from each other at another. **Polarine maintains a perfect film both at low temperatures and in intense heat.**

Low Cold Test:

Many oils congeal at low temperatures. This interferes with the operation of a car in cold weather. **Polarine flows freely down to zero.**

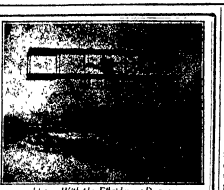
Carbon Proof:

Carbon deposit has long been the commonest cause of automobile troubles. We have succeeded in practically eliminating from lubricating oil the carbon forming elements. This makes a great forward stride in automobile lubricants. **Polarine gives practical freedom from carbon deposit.**

Polarine

The Polarine brand covers:

Polarine Oil, sold in sealed cans, gallon and five gallon sizes; or in half barrels and barrels.



Polarine Transmission Lubricants for transmissions and differentials, sold in three consistencies, in cans of convenient size, also in half barrels and barrels.

Polarine Cup Grease and Polarine Fibre Grease, the latter of high melting point, especially adapted to use on universal joints. Sold in round cans.

All dealers sell Polarine Lubricants or can get them for you.

If you own a motor car or motor boat send for our booklet, "Polarine Pointers." It includes hints on lubrication and the causes of motor troubles. Write our nearest agency.

Notes and Queries

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12474) R. L. says: IN SUPPLEMENT No. 1217, in an article on liquid air, the statement was made that liquid air could be poured over the hands without producing much sensation, on account of the heat of the hand forming a thin layer of gas between the hand and liquid air How long could the hand remain submerged without being damaged? A. The hand cannot remain submerged in liquid air for any time without being frosen. It can be put into liquid air and taken out again without injury if this is done so quickly that the heat of the hand cannot be absorbed by the cold liquid Heat cannot pass out of the hand in an instant 2 I have read several different times that the strength of iron and steel was doubled (that at ordinary temperature) when cooled to the temperature of liquid air Now then, why is it that tools made of a high grade of steel, such as saws and hammers, break very easily when they are at that temperature called frozen? A. The tensile strength of iron becomes approximately doubled at the temperature of liquid air. Lead becomes elastic like steel. Iron and steel become very brittle at such low temperatures, and break like glass by bending Tensile strength and flexibility are not similar properties. 3. In their search for a motor seasonably immune from stopping, why don't the flying machine men use the steam engine, such as are used on some automobiles? A. The weight of the steam boiler and engine with its supply of water is against it Thus far no one has been able to construct a steam engine anywhere near as light as the gasoline engine. 4 I have heard that a man in a balloon reached a height of seven miles above sea level What is the atmospheric pressure at that height? Is the oxygen proportion the same as at sea level? A. The highest balloon ascent of which we have a record is 34,450 feet. The barometer stood at 7 95 inches This is something less than seven miles We have no record of the composition of the air at that elevation. The kinetic theory of gases would indicate that there should be less oxygen at that altitude than at the level of the sea 5 The SCIENTIFIC AMERICAN has stated many times that the highest temperature attained by man was the electric arc (estimated at 5,000 degrees) I have here a calculation that seems to contradict that statement. Take the case of the oxygen hydrogen combustion, allowing 50 per cent excess oxygen to make complete combustion more certain 1 cubic foot 12,000 Deg Fahr In the combustion of carbon-oxygen the temperature is still greater. I obtain 15,494 degrees total, considerably hotter than the oxygen-hydrogen combustion under the same conditions What do you think of this? A We are not able to assent to the assumptions upon which your determinations of the temperatures reached by various combustions are based. Your results could be true only if all the heat were received and retained by the resulting gases and if all the gas were heated uniformly throughout, and that instantaneously All of which is impossible to attain Your results may be called potential temperatures, but nothing more They are far from actual The impossibility may be realised from the statement that oxygen and hydrogen begin to dissociate at 2700 deg F. and have reached their limit at 4500 deg F. At a temperature of 12,000 deg F. a chemical action of oxygen upon hydrogen is impossible. They would remain perfectly inert in each other's society It is impossible to give figures for the temperature limit in the cases you present Kent, in his "Mechanical Engineer's Pocket Book," new edition, pages 786-6, gives a formula for calculating the temperature of combustion of materials containing carbon, hydrogen, oxygen, and water vapor But he says that the temperatures obtained by experiment are below those obtained by calculation, for which he gives certain reasons We send the book for $5

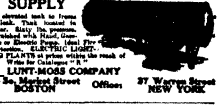
(12475) O. J. C. asks: We are occupying a steel concrete building here which was finished one year ago On the rear wall of our store room and basement we have had foil strips glued up and down on these walls, through which the current passes for the burglar protection Through either chemical action or moisture the current is at times interrupted that we cannot use the burglar protection, and the foil itself seems to have gone through a chemical process, so that it rubs off like powder Now what we wish to ask is if there is anything that you know of in the way of a thin covering that we can put over these walls so as to make them moisture-proof, and to which these foil strips can be attached, and work with satisfaction. A. A coating of shellac will render tinfoil moisture proof This is used in various electrical apparatus for this purpose, such as condensers, where it is very necessary to keep out the water. The shellac will act as a glue to make the foil adhere to the wall. The glue will not be necessary. The shellac is a good insulator also. Asphaltum varnish will serve the same purpose

(12476) H. O. S. asks: As I have always understood that any object that gives forth different tones by increased or decreased vibrations gives forth but one tone at any one instant or the smallest fraction of a second, will you kindly explain whether the reproducer of a talking machine, during a band selection, for instance, when several instruments are each making a different tone at the same instant, actually gives out the several tones at any instant, or apparently does so by the predominating tones following each other so rapidly in such a small fraction of a second that the ear is unable to realise it? A. The exact nature of the record in a talking machine is not clearly known. Much investigation has been spent upon it. Many papers have been published giving the reproductions of the tracings of the reproducers much enlarged. But the indentations are so minute and of so little depth, that very little progress has been made in this research. A very good report of this work may be found in the recent textbook of Sound by Prof. Barton of Nottingham. We will send the book postpaid for $2 It does not, however, answer your question. Perhaps the only certainty is that you actually hear the music of a band in the phonograph just as if you were listening to the instrument when the sound is directly transmitted through air. We are inclined to the opinion that the reproducer actually gives out the several tones just as they went into the recorder.

(12477) G. E. A. asks: How to find the specific gravity of water, and how to find out the difference in draft of a ship in salt water and fresh water. A. The specific gravity of fresh or pure water is 1. It is the material with which all other materials are compared, and hence is assumed as unity The specific gravity of sea water varies from 1 025 to 1 03, according to its degree of saltness A ship will displace the same weight of salt water as of fresh The fresh water would occupy the larger volume, and the ship would sink deeper in it. Taking the salt water as the usual medium for a ship to float in, and the volume of fresh water displaced by it will be 100/1000 of the volume of salt water displaced by it. As "draft" is the vertical depth from water line to lowest point of keel, the increased draft of ship in fresh water as compared with salt depends upon the shape of the ship One vessel might sink an extra inch and another a foot or two in fresh water By calculation from the hull drawings, marine engineers can determine the exact displacement of a ship at any depth of immersion. The weight of ship and cargo equals the weight of the displaced water. Therefore to move a ship from salt to fresh water changes its draft an amount equal to the change that would occur if the ship's total weight (including cargo) were increased by the specific gravity of salt water—1 025 to 1.03. In other words, it would draw as much more as if it were loaded an additional three per cent.

(12478) C. P. DuS. writes: Can you send me the alphabet commonly used in wireless service, with the name of an advertiser who will furnish me with an outfit? A. You will find the Morse and Continental alphabets used in the wireless telegraph in Collin's "Wireless Telegraph Handbook," which we send or $1 50. We must be excused from copying them when they are accessible in printed form.

(12479) P. W. B. asks: 1. What form of tuning fork, cylinder wire, or other mechanism, is the most sensitive to sounds produced by other means of a mechanical nature or the voice? A. A tuning fork mounted upon a proper resonant box, will take up and reproduce any sound of exactly the same period as its own, and so reproduce it. So too will a piano string, as you may prove by raising the loud pedal and singing a note into the piano. You will find several strings to be giving forth their tones, which are the overtones of your voice when singing that note. We do not know anything more sensitive than this. 2. Is there any instrument made, or how can I make, or have made an instrument that can be attuned to various sounds, as given on the piano, say, or on a harp, or violin? A. There is an instrument called the phonautograph which registers any tone spoken or sung into it. This you can learn about by addressing Queen & Co., 59 Fifth Avenue, New York. 3. What books are the best authority on acoustics? A. Sounds and methods of testing them out, or attuning other things to them? I am not up in this line, but am I a scientific man, other than from general reading but not from a mathematical standpoint, so something of a simple nature is apt to be of more value to me, and with this in mind, your reference will be gaged, if you please. A. The latest book on acoustics is Barton's "Textbook of Sound," which we will send for $3. It contains a chapter upon sound recorders and reproducers.



A PLAN for INVESTORS
We invite your inquiries regarding our plan for the purchase of Additional Working Capital for the Manufacturing, Selling and Operating Company, organized by Leavitt & Grant, which is now offering a limited amount of its 7% Preferred Stock at par and accrued dividends.
We will send, free upon request, descriptive literature, plan, which is worthy your careful consideration, and financial reports which absolutely establish the merit of this enterprise.

Lithopone and Its Manufacture

By S. Rose

ATTEMPTS had long been made to manufacture a real white paint of high covering power from baryte, otherwise known as heavy spar, which has been used largely as an adulterant to other white pigments. The various attempts met with success both in Germany and England when the substance commercially known as lithopone was made. It has also since been known by its other commercial names, such as Orr's white, Jersey Lily white, ponolith, oleum white, and others given by various manufacturers. It is a chemical compound, the constituents being zinc sulphide 29.5 per cent and barium sulphate 70.5 per cent. When fairly pure, solutions of known strength and proper temperature of zinc sulphate and barium sulphide are mixed in their molecular proportions, a heavy flocculent easily filtered precipitate is obtained according to the formula:

$$ZnSO_4 + BaS + H_2O = ZnS + BaSO_4 + H_2O.$$

This precipitate, however, has very little covering power. John B Orr, of England, discovered that when it is heated to a dull redness and suddenly plunged in cold water and then thoroughly ground, washed, and dried, it is completely changed into a new substance, although with no chemical change, far excelling in its qualities most of the white paints. The cause of this change is not well known. It seems probable that this treatment causes an internal re-arrangement of the molecules. The different commercial samples vary in their composition to a slight extent, and the modes of the manufacture are kept as trade secrets. In recent years the quality of the substance has been much improved and made uniform. There is no difficulty or much complication in its manufacture, success depending to a large extent on the purity of the substances used and those again are more or less easily prepared. But the manipulation must be carried on with care and knowledge, as otherwise the result will be unsatisfactory and the presence of impurities will make the paint colored and totally unfit for the purposes for which it is used.

The barium sulphide is made in the following way: About 100 parts of finely powdered baryte and 20 parts of coal slack or charcoal, petroleum residue, pitch, sawdust, or any other substance with a high percentage of carbon also finely powdered are mixed thoroughly and heated to dull redness without any contact with air. Asphalt of gas works is a capital reducing agent, as the hydrogen contained in it prevents the formation of polysulphides of barium. The argol residue from tartaric acid vats is also a good reducing agent. Another method used in some factories consists in mixing 100 parts baryte, 200 parts common salt, 15 parts charcoal powder, and roasting the materials in a reverberatory furnace, the salt being used to assist fusion. At the time of roasting the following reaction is supposed to take place:

$$BaSO_4 + 4C = BaS + 4CO.$$

When the reaction is complete, avoiding contact with air as much as possible, the barium sulphide is leached out after digesting the mass in vats and filtered. When the solution reaches a density of 17 degrees Beaume, long yellowish needle-like crystals separate out from the mother liquer, consisting of chemically pure barium sulphide. Any impurities in the baryte generally do not affect the purity of the barium sulphide formed. The metals, like copper, iron, and manganese that are occasionally present in the baryte, form insoluble sulphides, whereas barium sulphide is completely soluble. Barium sulphide has a hepatic odor and alkaline taste, and in water forms a mixture of barium hydrate and barium sulph-hydrate:

$$4BaS + 4H_2O = Ba(SH)_2 + Ba(OH)_2.$$

It should not be exposed long to the air, as it is then converted into Ba CO, and H_2S given off owing to absorption of moisture and CO_2.

With about 60 per cent concentration of the solutions and temperature of [illegible] deg. C., and when the zinc sulphate [illegible] vat will double the rate at which the BaS is poured we get a characteristic precipitate most easily filtered and dried. It is now placed in muffles and heated above 920 deg F., suddenly plunged into water, ground, washed thoroughly and dried and is ready for the market. Overheating should be avoided, as some of the ZnS then becomes converted into zinc oxide. Formerly 5 to 10 per cent of zinc oxide used to be present invariably in the commercial product, but as its presence decreases to a small extent the efficiency of the paint, the heating is so regulated that the percentage of zinc oxide present is very small.

Last year I carried on about twenty experiments in an attempt to make lithopone from baryte and the zinc carbonate mineral known as smithsonite and secured fairly good results. For reducing agent I used argol residue from tartaric acid vats containing about 95 per cent carbon. A slow prolonged heating to dull redness for about eight hours gave the best yield of BaS—about 56 per cent. Heating at a high temperature for three to four hours also gave fairly good, but somewhat low, results, varying from 40 to 48 per cent. The BaS was almost pure. For the manufacture of ZnSO4 from the carbonate, I got fairly satisfactory results from a method I devised. The ore was finely powdered and treated with crude H_2SO_4 and heated when a lumpy mass is formed and when hard it was powdered and roasted. There was about 2 per cent of iron in the ore which was oxidized and the zinc sulphate was then leached out by digesting with hot water. Another good method is to dissolve the mineral in H_2SO_4 and then treat the solution with bleaching powder and remove the precipitate by filtration, the iron being thus eliminated.

Lithopone has had quite a history in the market. When first brought out it was condemned as a hoax, as nobody would believe that BaSO4 could form a paint. But it has been able to outlive its condemnation by sheer merit. It is one of the most effective and durable of white paints. In the brilliant white of its color, its fine texture, and hiding power, it is scarcely surpassed by any one white paint, and change of weather or atmosphere has practically no effect on it. It finds use in many industries. It is indispensable and largely used in the manufacture of floor oil-cloth, as it does not oxidize in time, and also in the cheaper grades of enamel paints, as it does not combine with resin or semi resin varnishes. As a ready-made paint, it can be kept for an indefinite period in the package without deterioration. It is far better as a marine paint than zinc oxide and lead carbonate. Mr Toch, the well-known expert on paint, sums up its qualities in the following words: "As an interior white, a first-coat white, a ready-to-use flat paint for surface, or as a pigment in the lighter shades for floor paints, lithopone cannot be excelled for its body, durability, hardness, fineness of grain, and ease of application." Mr Toch also notices one peculiar habit, its photogenic property, i. e., its power to absorb light and give it out again. When it is mixed with linseed oil or varnish and then exposed to the direct rays of the sun, it turns grayish readily, and in shade regains its normal color. The reason of this is not known. But Prof. Ostwald has succeeded in eliminating this power of lithopone, and the discovery is covered with patents. Some chemists have tried to explain this by saying that the coloration was due to lead forming a lead sulphide. But this does not seem to be a satisfactory explanation, for in the manufacture of floor oil-cloth lead driers are always used and no coloration results, and moreover ZnS seldom liberates its sulphur in the presence of any neutral salt, and so strong is the chemical union that it is perfectly stable in the presence of organic acids.

It is rather interesting to know that BaSO4 is regarded in this country as an adulterant, thus lowering the value of a paint containing it, whereas in Europe its presence in paints, especially white lead, is valued for its whiteness, elasticity, on account of its insolubility in acids, its greater covering power, and

VACUUM CLEANERS
Broomell's Victor Stationary

We manufacture Electric Stationary Cleaners for buildings of any size or kind.
We make a specialty of residence work, and our machines can be installed in old or new houses without expert help.
We manufacture a Stationary for use with Gasoline Engine or other power, especially adapted to country homes.
The VICTOR Electric Portable is a very powerful handsomely finished machine. *"T'is the finest in the land"*

its resistance to atmospheric gases and changes of weather. Baryte is now an important mineral for its extensive industrial uses It is used in the manufacture of paper and rope to give weight, and it forms a covering to canvas sacks in which ham is sent to the market. The carbonate mineral witherite used to be the chief source of Ba(OH)$_2$, but owing to its rarity in commercial quantities baryte has become the source of other barium compounds The greatest possible use of baryte is in beet-sugar industry in the separation of sugar from molasses, and some claim that it is also applicable to cane sugar industry It is also used to purify water in steam boilers and in the preparation of hides in tanning It occurs extensively in this country in Missouri, North Carolina, Tennessee, Illinois, Kentucky, Virginia, but the annual production is rather small—about 61,668 short tons, value $203,154 (1902), of which more than half came from Missouri It is also imported in small quantities from outside.

Aviation Sickness

MODERN progress is not without its drawbacks, as would appear from the fact that after being familiar with mountain sickness, we are now to have the "aviator's sickness" inflicted upon us This expression does not mean any slight upon the numerous contingent of aeroplane flyers, but is an actual sickness which is felt by aeronauts, and Dr. Dastre spoke about it at one of the meetings of the French Academy of Sciences Several doctors were at work observing it recently and especially during the Bordeaux aeronautic week They noticed the effect upon the pilots of aeroplanes when flying very high, and also mounting or coming down very quickly When mounting in the air, they find that breathing becomes shorter when at 5,000 feet height, and this effect is more noticeable than with ordinary balloons The heart is noticed to beat faster, but generally there are no palpitations, and there is only a slight ill feeling which the aviator Morane thinks is a nervous sensation due to anxiety and the emptiness of space Buzzing in the ears is noticed only at a greater height, about 6,000 feet, although Legagneux felt a cracking noise in the ears when flying lower than this According to Morane, the view is always very clear, but another flyer had veritable hallucinations on one of his trips, and at each instant he imagined that he saw the tower of Notre Dame on his right, although he was hundreds of miles from Paris

When flying at 3,500 feet, and especially above 5,000 feet, the reflex movements of the system have a greater amplitude This appears to be due to a combination of causes, such as cold, a more rapid breathing, quicker heart beats the effect of sunlight and troubles of hearing, to which we must add nervous tension and fatigue The doctors also noticed what were the effects of a rapid descent in an aeroplane, and these appear to be a burning sensation in the face and redness One curious effect is a great tendency to sleep, and this is so strong that the eyes sometimes close in spite of all efforts to keep them open We must take it on the authority of Dr. Dastre that not long since a young pilot started out on an aeroplane flight, and was afterwards found fast asleep in the open fields When awakened, he did not remember how he had come down. Thus the different kinds of "aviator's sickness" are likely to give some startling results

High Tension Discharge Apparatus

AT the recent soiree of the Royal Society, Prof E Wilson and Mr W. H. Wilson exhibited an improved high tension discharge apparatus. Energy is stored in a magnetic field by inductance, from a low frequency circuit, and in so stored the condenser is mechanically bridged across the primary winding of an induction coil, thus forming a high frequency oscillating circuit The energy is then transferred by the secondary winding to the work circuit. The above cycle of events is controlled by a motor-driven interrupter. Tapping points on the inductance winding allow of a suitable range of voltages being used.

Aeronautics

Detroit Aviation Meet.—About $15,000 has been raised for prizes for the Detroit meet, which is to be held for 6 days from June 30th to July 4th inclusive.

Aeroplanes in Department Stores.—As he was the first to exhibit a Blériot monoplane in his stores in New York and Philadelphia, so John Wanamaker is also the first to put an aeroplane on sale in his New York store. He is exhibiting there a Moisant monoplane of the Blériot type, which is shown equipped with an Anzani motor for the sum of $4,000 There is also on exhibition an imported French balloon, the price of which is but $1,500. It is probable that other department stores will adopt this idea, which will enable ardent aviators to purchase machines at a moment's notice, if not to fly them as quickly.

The International Speed Race.—For the third time the French will try to capture the Bennett trophy in England on July 1st. France has a better team this year than ever before. Alfred Leblanc will again pilot a 100 horse-power Blériot and will have as team mates M. Edouard Nieuport and M. Chevalier on Nieuport monoplanes, which machine holds the record for nearly the distance of the race—145 kilometers—at 80 miles an hour Auburn will be the substitute if any is needed To defend the cup England will have Gustave Hamel with a 100 horse-power Blériot, Alex. Ogilvie with a powerful "baby" Wright, and one other aviator yet to be chosen. America will have only Charles T Weymann, who, nevertheless, stands a good chance with a fast Nieuport monoplane Austria will send Herr Flesch, with a fast monoplane, and Germany will also be represented The race will be run at Eastchurch, Isle of Sheppey, and will start at 11·46½ A. M.

Hamilton Flies Around the Connecticut State Capitol.—Emulating Tom Sopwith's flight around the Philadelphia city hall recently, Chas K Hamilton flew about 10 miles from New Britain, Conn. (his home town), to Hartford, where he circled several times the 274 foot-high dome of the capitol before flying over the heart of the city and continuing for 15 miles farther up the Connecticut River toward Springfield. Hamilton turned without alighting and flew back home. His flight was a demonstration of the freedom of the aviator. After Jan. 1st, 1912, all aviators, balloonists and dirigible pilots must obtain a license in order to fly in the Nutmeg State, and no one under 21 years of age can enjoy any of these sports. This is in accordance with the provisions of the bill drafted by A. Holland Forbes and recently rushed through the Connecticut legislature. Having fallen through the roof of a house once himself the famous balloonist wants to protect his fellow citizens, as far as possible, from the chance of any such accident.

The Waltham, Mass., Meet.—The second aviation meet to be held near Boston occurred at Waltham from June 15th to the 20th. Jas. V Martin, who has lately returned from England with his wife, who is also a flier, made some excellent exhibition flights with a Blériot monoplane and a Burgess biplane. Ovington made several sensational flights over Waltham, Boston, and the surrounding towns In his longest flight across Boston he was gone half an hour. He flew across the city and out over the harbor and back Harry Atwood with his Burgess-Wright biplane made a number of cross-country trips with passengers, the chief of which was his trip to Concord, N. H, with a passenger. He flew in a very strong wind and stopped to change passengers at Lowell, Nashua, and Manchester. He covered 75 miles in about two hours flying time The following day he flew still farther with another passenger Atwood's flights in a Wright machine in a strong wind are in line with the performance of Ogilvie in an S.E.C.-engined Wright in England recently, when the wind was so strong that the aeroplane hovered above a given spot but could make no forward progress.

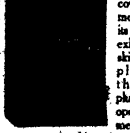
New Practical Books

Popular Hand Book for Cement and Concrete Users.

By MYRON H. LEWIS, C. E., and ALBERT M. CHANDLER, C. E. Octavo, 450 pages, 126 illustrations. *Price, $2.50.*

¶ A concise and comprehensive treatise on the principles and methods employed in the manufacture and use of concrete and its products in all classes of modern works. It is a standard work of reference covering the various uses of concrete both plain and reinforced. Everything of value to the concrete user is given, including kinds of cement employed in construction, concrete architecture, inspection and testing, waterproofing, coloring and painting, rules, tables, working and cost data. It is a thoroughly practical work, clearly written, systematic and logical in its arrangement, broad in its scope and gives a lucid explanation of, and a clear insight into the fundamental principles employed in concrete design and construction. The practical value of the book is enhanced by over thirty-five useful tables, and concise statements of rules and methods.

Drop Forging, Die Sinking and Machine Forming of Steel



By JOSEPH V. WOODWORTH, author of "Dies, Their Construction and Use," "Punches, Dies and Tools for Manufacturing in Presses," etc. Octavo, 340 pages, 300 illustrations. *Price, $3.50.*

¶ A complete practical treatise on the hot and cold machine forming of steel and iron into finished shapes, together with the tools, dies and machinery involved in the manufacture of duplicate forgings and interchangeable hot and cold pressed parts from bar and sheet metal. It is a comprehensive and modern work, written by an expert, and treating fully on modern shop practice, processes, methods, machines, tools and details.

Standard Practical Plumbing

By R. M. STARBUCK, author of "Modern Plumbing Illustrated," etc. Octavo, 406 pages, 347 illustrations. *Price, $3.00.*

¶ This is a complete practical treatise and covers the subject of modern plumbing in all its branches. It treats exhaustively on the skilled work of the plumber and the theory underlying plumbing devices and operations, and commends itself at once to everyone working in any branch of the plumbing trade. A large amount of space is devoted to a very complete and practical treatment of the subjects of hot water supply, circulation and range boiler work. Another valuable feature is the special chapter on drawing for plumbers. The illustrations, of which there are three hundred and forty-seven, one hundred being full page plates, were drawn expressly for this book and show the most modern and best American practice in plumbing construction.

Any of these books will be sent, postpaid, on receipt of advertised price

Wizard Repeating LIQUID PISTOL
Will stop the most vicious dog or man instantaneously. Can be fired with or without ammunition. Entirely harmless. Effective by putting the weapon close to the object to be fired upon. Guaranteed not to injure the weapon. Loads from the breech. Length 6 inches. Nickel finished. Sent, postpaid, to any address in the U. S. for $1.00. Circular free. Agents wanted. Address, Wizard Mfg. Co., 1440 Bedford Avenue, Brooklyn, N. Y.

BAKELITE

Electricity

Telephone Train Dispatching on the Lehigh Valley.—A large part of the Lehigh Valley Railroad now uses the telephone for train dispatching. It was decided recently to extend this system to practically the entire road. An order has been placed for the apparatus, and with the exception of a short stretch of ninety miles on the West Buffalo Division, the entire Lehigh Railroad will soon be using the telephone train dispatching apparatus.

Electric Lights in the Society Islands.—According to a recent consular report, an American living at Papeete, in the Society Islands, has installed an electric lighting system in the city. He has placed at the street crossings 100 candle-power lamps, with 40 candle-power lamps at other points. The lights are very astonishing to the natives, who travel miles to see them. The plant consists of two 30-kilowatt generators, one 10-kilowatt generator, and one 5-kilowatt generator, with a total capacity of 3,000 20 candle-power lamps.

Mining Gold with Electric Dredges.—More than twenty-five per cent of the gold mined in California is now recovered by means of dredges. Formerly the dredges were operated by steam power, but this was expensive owing to the scarcity of fuel. Now that California is utilizing its streams for the generation of electricity, electric power is available throughout the State at low costs. Gold dredges are accordingly being equipped with electric motors, which have not only proved more economical but have shown themselves to be more adaptable for this class of work because of their ability to run continuously without much attention and with almost perfect reliability.

Pilot Cells for Electric Vehicle Batteries.—It is not always possible to judge accurately of the condition of a battery with a voltmeter, particularly if the battery is not new. Heretofore, however, this has been practically the only method that could be used, for the reason that the cells are sealed and it is a difficult matter to reach the electrolyte for the hydrometer tests. As however the hydrometer test is the only reliable one, a storage battery manufacturer has recently brought out a pilot cell in which a hydrometer is permanently incased behind a small glass-covered opening. Readings may be taken at any time and a card attached at one side of the battery shows the mileage available for different gravities.

Protecting Pipes Against Electrolysis.—It is well known that underground pipes are injured, not when stray currents enter them, but when they leave them. Such being the case, the city of Karlsruhe, in Germany, has used a system which will prevent a stray current from leaving the pipe. A set of plates and pipes are buried close to the water pipe at the points where electrolysis is liable to occur, and these are connected to the positive pole of a storage battery or generator, while the water pipe is connected to the negative pole. As the voltage of the stray currents that produce electrolysis is usually quite low, the expenditure of power required to maintain the requisite current in the water pipe is not costly. So far this system has proved very efficient.

Measuring Candle Power with a Thermopile.—In a paper read before the London Royal Society, of recent date, A. R. Houstoun referred to a system for measuring candle power by means of the thermopile. Ordinarily this is impossible owing to the fact that the thermopile is affected by invisible as well as the visible waves. However, it was found that by using a light filter consisting of solutions of copper sulphate and potassium bichromate the ultra-violet and infra-red rays are entirely stopped so that only the visible portion of the spectrum passes through and impinges upon the thermopile. The author suggests that this means be used for measuring the intensity of light, employing as a unit that intensity which would produce 0.8 erg per square meter per second at a distance of one meter.

Science

Michelsen Honored at Goettingen.—The University of Goettingen on June 15th conferred the honorary degree of doctor of philosophy upon Prof. Albert A. Michelsen, of the University of Chicago, and exchange professor at Goettingen.

Wolf's Periodic Comet.—A cablegram has been received at Harvard College Observatory from Kiel stating that Wolf's Periodic Comet was observed by Prof. Max Wolf at Heidelberg, 1911, June 19 4752 in R A 18 h 46 m 16s, Dec +12° 28'. The comet is visible in a large telescope.

Anti-Typhoid Vaccination in the Army.—On the recommendation of Major General Leonard Wood, Chief of Staff, the Secretary of War has ordered that anti-typhoid vaccination, which for more than a year has been voluntary in the army, shall be administered to all recruits except those over 25 years of age.

An Expedition to Jan Mayen.—The American Geographical Society has received notice that Mr. J. Foster Stackhouse, of England, has organized an expedition to visit, during the present summer, the island of Jan Mayen, which lies far to the northeast of Iceland, in the direction of Spitzbergen. With the expedition will go, as geologist, Mr. W. S. C. Russell, of the Central High School, Springfield, Mass. Jan Mayen was one of the points occupied by the international polar expeditions of 1882-1883, viz., by the Austrian expedition under Wohlgemuth.

Wireless Communication with Spitzbergen.—Roughly speaking, Spitzbergen lies a thousand miles north of the Arctic Circle, but, in contrast to other regions of equally high latitude, it has become the field of active exploitation. Its coal mines are being worked most profitably, and it is now visited every summer not only by the fishing-fleets, but by large parties of tourists. The great need of telegraphic communication is about to be met by the Norwegian government, which has decided to establish a wireless station at Green Harbor. The nearest point of wireless communication will be Hammerfest, 750 miles distant.

Meteorological Stations in the South Pacific.—The director of the Chilean meteorological service, Dr. Walter Knoche, recently began a cruise on the naval schoolship "General Baquedano" in the course of which he was to establish a first order meteorological station on Easter Island, the most easterly Island of Polynesia. It is intended to keep this station in operation for at least two or three years. Seismological observations will shortly be undertaken at the same point, under the direction of the Chilean Seismological Institute. On his return voyage Dr. Knoche expected to stop at the island of Juan Fernandez, where, if possible, another meteorological and seismological station was to be established. As this island is to have wireless telegraphic communication with the mainland, it is probable that Juan Fernandez (the locale of "Robinson Crusoe") will become an important outpost of the weather forecasting service of Chile.

Amundsen's Antarctic Expedition.—As already reported in this journal, Capt. Amundsen, who left Norway ostensibly for the Arctic regions, where he proposed to make a five years' drift across the Polar Sea, recently turned up, to the surprise of the scientific world, in the Antarctic, where he was found by the English ship "Terra Nova" preparing for an attack on the south pole. His change of plans has now been explained by Dr. Nansen, in a letter to the London *Times*. It appears that he wrote to Nansen from Madeira that, owing to the diminished popular interest in the north pole since the successful result of Peary's last expedition, he felt convinced that he should not be able to raise sufficient money for the proposed long voyage in the Arctic. He therefore decided upon the more popular and less expensive plan of vying with Scott, Filchner and the others in a dash for the south pole. A press dispatch, dated June 17th, states that Pedro Christophersen, a Norwegian in business in Argentina, has agreed to finance Amundsen's expedition to the extent of $50,000.

A Guaranteed First Mortgage Bond
Netting 6%

An issue of $250,000 secured by an exceptionally efficient water power development and modern plant located in one of the most rapidly growing and prosperous sections of the United States.

1. The security is conservatively valued at $700,000 the bonds being issued at the extremely conservative rate of $50 per horse power developed.
2. In accordance with our usual plan, the bonds mature serially and the margin of security will rapidly increase.
3. Net earnings of several times the average annual requirements for principal and interest are protected by contracts with reliable concerns.
4. The bonds are guaranteed and this guarantee places behind them additional assets worth nearly three times the amount of the issue.

A developed water power is a perpetual income-producing asset of increasing value, and we strongly recommend the bonds of this issue for investors seeking a conservative investment for their July funds.

Co-operation and Enthusiasm

Are evident in the manner in which our subscribers have responded to our request for the names of people whom the Scientific American should interest. We have received thousands of names and as a result we have had the pleasure of extending the subscriptions of a large number of our friends. Have you sent us a list? If not

Here is the way:

Simply send us the names and addresses of the people whom you think will be interested in the Scientific American and we will do the rest. An accurate record of all names received in this manner will be kept, and for each new subscription we get from any list we will extend the subscription of the person who sent us the list for four months. Thus if we receive three new subscriptions from any one list the subscription of the person who sent us the list will be extended for a full year.

Of course, you may send as many names as you wish, the greater the number of names you send the larger the number of subscriptions we will probably receive and the longer the period for which your own subscription will be renewed.

Be careful to write the names and addresses plainly and don't fail to put your own name and the address at which you are receiving the Scientific American on each list you send.

Address all lists to the Circulation Department, Scientific American, 361 Broadway, New York City.

The Scientific American Cyclopedia of Formulas

The Most Complete and Authoritative Book of Receipts Published

Partly Based on the Twenty-Eighth Edition of "The Scientific American Cyclopedia of Receipts, Notes and Queries"

Edited by **ALBERT A. HOPKINS,** Query Editor of the Scientific American

THIS is practically a *new book* and has called for the work of a corps of specialists for more than two years. Over 15,000 of the most useful formulas and processes, carefully selected from a collection of nearly 150,000, are contained in this most valuable volume, nearly every branch of the useful arts being represented. Never before has such a large collection of really valuable formulas, useful to everyone, been offered to the public. The formulas are classified and arranged into chapters containing related subjects, while a complete index, made by professional librarians, renders it easy to find any formula desired.

"As Indispensable as a Dictionary and More Useful"

Following is a List of the Chapters:

I. Accidents and Emergencies.
II. Agriculture.
III. Alloys and Amalgams.
IV. Art and Artists' Materials.
V. Beverages; Non-Alcoholic and Alcoholic.
VI Cleansing, Bleaching, Renovating and Protecting.
VII. Cements, Glues, Pastes and Mucilages.
VIII. Coloring of Metals, Bronzing, etc.
IX. Dyeing.
X. Electrometallurgy and Coating of Metals.
XI Glass
XII. Heat Treatment of Metals.
XIII. Household Formulas.
XIV. Ice Cream and Confectionery.
XV. Insecticides, Extermination of Vermin
XVI. Lapidary Art, Bone, Ivory, etc.
XVII. Leather.
XVIII. Lubricants.
XIX. Paints, Varnishes, etc.
XX. Photography.
XXI. Preserving, Canning, Pickling, etc.
XXII. Rubber, Gutta-Percha and Celluloid
XXIII. Soaps and Candles.
XXIV. Soldering.
XXV. Toilet Preparations, including Perfumery.
XXVI. Waterproofing and Fireproofing.
XXVII. Writing Material.
Appendix: Miscellaneous Formulas; Chemical Manipulation; Weights and Measures; Index.

MONOPLANES and BIPLANES

THEIR DESIGN, CONSTRUCTION & OPERATION

The Application of Aerodynamic Theory, with a Complete Description and Comparison of the Notable Types

By **GROVER CLEVELAND LOENING, B.Sc., A.M., C. E.**

CRITICISMS

"The first treatise upon aviation which we have seen which may be styled really complete. . . . Actial aeroplane designing is the central theme of the volume. . . . . The prominent types are exhaustively compared. . . . . The illustrations are a notable feature."
—*Rochester, N. Y., Chronicle.*

"A very complete account of the theory of heavier than air flying machines with a technical description of nearly all the present types of aeroplanes. . . . . Presents in compact shape the substance of aeradynamic theory. . . . . Easily comprehensible to the reader who can concentrate his attention. . . . . It is the most scientific popular book on the aeroplane that we have come across so far."
—*New York Sun.*

"Many writers have failed to realize the demand which exists for such literature in which mathematical deductions are a necessary but not predominant part of a comprehensive exposition of the same subject. For a writer to steer a straight course between the mazes of trigonometry on the one hand, and the superficialities of mere discussion in a popular vein on the other is to accomplish what can be done only by one who is himself a thorough student in the finer details, but who can sufficiently divorce himself from the mathematical atmosphere as to present the whole subject from a broad standpoint, making it readily intelligible and informative to the less erudite seeker after knowledge."
—*Philadelphia Inquirer.*

"Students learned in aerodynamics and laymen ordinarily interested in aviation will find equal delight in reading 'Monoplanes and Biplanes.' The book is a welcome addition to the libraries of those who have realized the future of aerial navigation, and desire a work treating solely of the theories that air machines written by an acknowledged expert—and with no hobbies hidden in the discussion."
—*Boston Journal.*

"While enthusiastic in his interest as becomes one who has written to unearth a volume, Mr. Loening is also rapidly assumes as the most exacting scientist could demand. Here is a work which is at once a history and textbook which may be depended upon for everything that is within the range of actual knowledge. To say that 'Monoplanes and Biplanes' is at once new and authoritative with reference to the entire subject and that it is practical in the highest degree is the just praise due to this volume."—*Buffalo News.*

"Mr. Loening has written, in fact, for the man who wishes to apply practically the experience that has already been gained."
—*New York Times.*

12mo. (6x8¾ inches) 308 Pages, 276 Illustrations. Appendix and Complete Index.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are shown, the articles stand, and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately and in simple terms, the world's progress in scientific knowledge and industrial achievement. It seeks to present this information in a form so readable and readily understood, as to set forth and emphasize the inherent charm and fascination of science

The Subway Muddle

A FEW years since the SCIENTIFIC AMERICAN had much to say about the development of New York's system of subways. For the past year or two, as our readers know, we have been silent on the question, and this for the reason that we have found it practically impossible to suggest any best way out of the maze of opposing schemes which have been presented and discussed. When the idea of building the Tri-borough Subway took definite form, we had hoped that out of the melting pot into which the propositions and counter-propositions of the Public Service Commission and the Interborough and Brooklyn Rapid Transit Companies had been cast by the city officials, there would have come a comprehensive and acceptable scheme which would serve the best interests, both of the public and the operating company. But we have to confess that the practical results, if they may be called such, seem to us at the present writing to be decidedly disappointing.

After a careful consideration of the discussions of the past few months, we find ourselves more and more inclined to agree with our practical and far-sighted Mayor, in his conviction that the best policy of the city would be to permit the Interborough, the present operating company, to build all the needed extensions in Manhattan, the Bronx, Brooklyn, and Long Island, and operate them for a single five-cent fare. But we would attach to this proposition a most important clause—namely, that the hands of the Public Service Commission should be strengthened to give them such an immediate control of the operating features of the road that the comfort, convenience, and proper self-respect of the traveling public, will be absolutely safeguarded.

But let it be understood, just here, that we hold no brief for the Interborough Company. On the contrary, we believe that their extreme unpopularity, of which they must surely be very well aware, is fully deserved, being due to the obstructionist attitude which they have shown to the requests of the New York public as expressed through its representatives, the Public Service Commission, notably in the matter of providing accommodations in those intervals between the rush hours, in which, if the Interborough had shown a friendly and reasonable attitude, it could easily have provided a seat for practically every passenger. There was a period of several months during which the attitude of the Interborough to its patrons, as expressed in their obstructionist policy to the Public Service Commission, was one of supercilious contempt and total disregard either for their convenience or comfort.

On the other hand, we wish it to be clearly understood that on the purely physical, the engineering side, we consider the work of the Interborough in perfecting its system to have been simply magnificent. In no other city can there be found twenty-five miles of road which, in the combined speed and number of its trains, in the perfection of its signaling system, in the multiplication of safeguards against disaster, and in the enormous multitudes that are carried day in and day out, with practically no accidents whatever, can compare with the New York subway as operated by the Interborough Company.

In the effort to get the largest number of trains over their tracks in the shortest possible time, the company appear to have made cost the last consideration.

In view of the above facts, it is simply amazing that they should have shown such a "picayune" spirit, in hastening to cut off cars the moment the rush hour was over, and at the very time when the wonderfully patient New Yorker would naturally look for a seat.

Now the Interborough Company is extremely anxious to build the whole subway system as originally laid out by the Rapid Transit Commission, with such further enlargements as the growth of the city and the demands of Brooklyn and Staten Island have made imperative. With paste pot and placard they have spread their appeal on car and platform, and elevated pillar. There is no question whatever about the anxiety of the Interborough to keep out every competitor and build a "five-borough route operated for a five-cent fare."

But this slogan of the Interborough is nothing more nor less than the dream of the average workaday citizen of New York. He wants it badly, but he also wants it comfortably, decently, and rid of those brutalities which disgrace the Interborough's present methods of handling their passengers. The ten-car train in rush hours has done much to mitigate the horrors of subway travel; the eight-car train between rush hours would have a similar effect. The average citizen cares very little who builds, owns, or operates a "five-borough, five-cent" system; but he cares very much indeed whether the system is to be operated along the lines of disgusting indecency which mark the present methods, and he demands that whatever new system may be built, it shall be no longer necessary, when he gives up his five-cent fare, to also forego his self-respect, his elementary sense of decency and his native inborn chivalry toward women.

Now the SCIENTIFIC AMERICAN pointed out some months ago that the reasonable comfort of the passenger could be secured if the representatives of the traveling public, namely, the Public Service Commission, were empowered to see that their mandates were carried out to the letter by the operating company. To do this, it would be necessary merely to insert a clause in the contract with the operators of the subway, to the effect that whenever an employee, big or little, of the operating company, became obnoxious through failure to follow the orders of the Public Service Commission, the Commission would have power to summarily dismiss him, be he train-guard, center rush at car doors, or general manager.

Such a clause is to be found to-day in the printed forms of contracts for big city works—bridges, public buildings, etc. The same policy is followed in all great railroad contracts throughout the country. It works like a charm. What the chief engineer says, goes, and it is extremely rare for him to have to exert the drastic authority with which he is invested.

So the SCIENTIFIC AMERICAN would suggest that the Interborough Company be permitted to carry out the programme of construction which it has so prayerfully submitted to its long-time pushed and elbowed and buffeted patrons, with the understanding, however, that they, the patrons, are to be placed in a position where they can demand and enforce every possible consideration as to accommodation and courteous treatment that the exigencies of the situation will allow.

Necessity and Invention

ANYONE who scans a copy of the *Patent Office Gazette* with the notion that necessity is the mother of the entire brood of inventions therein contained, is destined to receive a rude shock. What an enormous family! Nine hundred and ninety-seven thousand to date, and increasing at the rate of six hundred new little necessities each week! But what an odd and varied brood, and are they all really necessities? Here is a strange one that was actually patented—a scheme for controlling horses by electricity. If the animal balks, a powerful and well-placed shock will make him spring forward in spite of himself. If he tries to kick, his muscles will be cramped by a paralyzing charge of electricity. Instead of bridle and reins, the all-powerful current may be used to give him a shock on the left cheek in order to turn into the right fork of the road, or on the right to make him take a left turn. Instead of sawing away at the lines, the driver may sit back in comfort, and, by means of push-buttons, typewrite the beast into submission.

Needless to say, this weird invention is an intruder in Mother Necessity's family. Alas! there are many such intruders. But a large number of inventions equally unnecessary are not so palpably foolish. The worst offender is the man who is not content with developing and improving the arts in which he is regularly employed, but feels that he must do missionary work in strange and unfamiliar territory. A farmer who has never been beyond the boundary of his own county will invent fire escapes for skyscrapers. A city clerk whose knowledge of the country has been gained from a trip to Bronx Park will invent an automobile plow. Sailors on the high seas will tackle the baffling problem of making safe rail joints, while the man from the Middle West almost invariably turns his attention to ship propellers and wave motors. An idea comes to such a man and he hastens to the Patent Office with it. It may be that he will give it a superficial examination; but the chances are that he will think it unnecessary to make his examination thorough, or else he will be afraid of divulging his secret by too searching an investigation.

Not long ago a man was struck with the brilliant conception of having rotary heels on shoes, the idea being that the wear would be evenly distributed and that the heels would not be run down on one side. The invention seemed so original to him that he thought it unnecessary to investigate the state of the art; however, he was persuaded to have a search of the Patent Office made, and much to his astonishment he found an entire sub-class devoted to this one particular branch of shoe-making, in which scores of patents had been secured on every phase of the idea. Of course this inventor's design was slightly different from the rest, and he might have secured a patent with a limited claim or two; but he was wise enough to see that his scheme was not necessary, and was therefore useless.

Until he has discovered the fact by rude personal experience, it is usually hopeless to tell a man with an idea that his invention is unnecessary. A man who is dabbling in arts of which he knows little or nothing will not listen to advice. You cannot tell him that invention, like charity, begins at home, because it does not, always. There have been exceptions, and notable ones, too, in which a man who is unfamiliar with a process or machine for doing a certain kind of work has attacked the problem from an entirely original point of view, and has developed an improvement of great value. It is these exceptions that encourage the precipitate man to begin invention in foreign fields.

We do not wish to create the impression that it is only the necessary invention that is worth while. Many of them appear unnecessary, and actually are unnecessary until the necessity for them has been naturally or artificially created. Many years ago a thin, emaciated young man in Boston who was literally starving, spent all his time with a series of experiments that seemed absolutely worthless. He carried his investigation so far as to employ a mummied human ear, and many an evening he spent whispering in this ghastly ear, trying to record the vibrations of the ear drum. The outcome of these experiments is the telephone of to-day. It was an unnecessary invention when first patented, a scientific toy, and no one seemed to see any particular value in it; but the need for it was built up after the invention was made. Verily, the successful inventor must be prophetic, in seeing a real necessity for his device, and the preliminary to success lies in careful, painstaking study and a thorough knowledge of every phase of the art.

The Bad Spelling of the Great

THE numerous members of the rank and file of humanity who have trouble in remembering the number of *n's* and *t's* in "Britannica" will derive much consolation from examining a pamphlet recently circulated by the publishers of the new edition of the world's greatest encyclopædia. This pamphlet contains facsimile reproductions of letters received from eminent people—college presidents and professors, judges, senators, and others—expressing their appreciation of the new work. Of seventy letters, some typed and the rest in autograph, no less than seven—ten per cent—misspell the word "Britannica."

So far as the purely scientific vocabulary is concerned, probably the word more often misspelled than any other is "sidereal." We notice that *Science reports the fact* that Prof. Svante Arrhenius recently lectured before the Washington Academy of Science on "The Siderial Cultus," and this announcement has been copied, in its original orthography, in the *Bulletin of the American Geographical Society*. As it happens this little slip on the part of two usually impeccable publications was entirely gratuitous, for the reason that the distinguished Swedish savant changed his programme at the last moment, and delivered a lecture on "The Atmosphere of the Planets."

George Ellery Hale

America's Foremost Solar Physicist

By Frederick Slocum of the Yerkes Observatory Staff

IN the report of the president of the Carnegie Institution of Washington for 1905 appears a list of the departments of scientific investigation to which the larger grants were assigned and the amounts of those grants. The sum of the sixteen grants mentioned is $304,500. One item in the list is "Solar Observatory, $150,000." According to the report for the next year a second grant of an equal amount was made to the Solar Observatory, and in each of the subsequent years large amounts have been assigned to the same institution. This fact has a two-fold significance; first, it shows the importance of solar research and the allied investigations which tend to interpret the universe, and secondly, it signifies the great faith of the trustees of the Carnegie Institution in the one man who was selected to build and direct its great Solar Observatory. This man was Prof George Ellery Hale of Chicago. Prof. Hale was born in Chicago in 1868. He received his collegiate education at the Massachusetts Institute of Technology, from which he obtained the degree of B.S. in 1890. While in college he had been especially interested in physics, and particularly that part of physics which involves spectroscopy. In 1892 he established a private physical laboratory in Chicago, which was known as the Kenwood Physical Observatory. In all of his mechanical and scientific tests a thorough course in manual training stood him in good stead, and he was especially fortunate in having the constant encouragement of his father, a successful inventor, manufacturer and business man. In 1891 the observatory was equipped with a 12-inch Brashear telescope and a powerful spectroscope. Prof. Hale's program, as announced at the dedication of his private observatory in 1891, called for "a thorough study of solar phenomena and particularly spectroscopic investigations of the spots, chromosphere, and prominences." For twenty years this program has formed the basis of all of his researches, and the success which he has achieved has completely revolutionized the methods of solar investigation as well as the interpretation of solar phenomena.

While still a student at the Massachusetts Institute of Technology Hale became interested in the study of the sun, and published several articles on that subject in the Massachusetts Institute of Technology *Quarterly* and in the *Astronomische Nachrichten*.

The particular phase of solar research that interested him at that time was the study of prominences. For years these objects had been observed only during total eclipses of the sun. After the eclipse of 1868 Janssen and Lockyer had independently discovered a method of using the spectroscope so as to render the prominences visible in full sunlight. Prof. Hale attacked the problem of photographing the prominences. His first experiments were performed at the Harvard College Observatory in 1889 and 1890, but met with poor success. His failure, however, was due to inadequate apparatus for his special problem rather than to any fault in his method, and this led to the construction and equipment of the Kenwood Astrophysical Observatory in 1891.

Within a year from the time this observatory was dedicated the problem was solved by the invention of an instrument called by Prof. Hale a *spectrohelioscope*. Without going into the technical details of this instrument, it may be described as a spectroscope so modified that any single line of a spectrum may be isolated and a photograph taken in the light of the element which produces the line. The spectrum of a solar prominence consists chiefly of the lines of hydrogen, helium and calcium. Using the *K* line of the latter element, Prof. Hale succeeded in making beautiful prominence photographs. A single exposure of two or three minutes' duration gave a record of all the prominences around the edge of the sun. By taking successive photographs at any convenient interval the changes in shape and general behavior of these most interesting solar features could be studied at will.

As soon as the spectrohelioscope was put into practical use it was found that the photography of the prominences was only one of many lines of solar research to which it was adapted. It rendered possible the photography of the sun in the light of any one of the elements which are conspicuous on its surface. These photographs show not only the distribution of such elements as hydrogen and calcium over the sun's surface, and the changes in this distribution from day to day, but also show how the clouds of the different gases vary in size, shape and distribution at different heights above the surface of the sun.

The spectrohelioscope opened up a new and wide field of solar research. Before it had been in use a year many new phenomena were discovered and many new theories of old phenomena were suggested. These brought honors in abundance to Prof. Hale. In 1895 the French Academy of Sciences awarded him the Janssen medal "for the construction and use of the first successful spectrohelioscope." This was followed, in 1902, by the Rumford medal of the American Academy of Science, in 1903 by the Draper medal

PROF. GEORGE ELLERY HALE

Director of the Mount Wilson Solar Observatory.

of the National Academy of Sciences, and in 1904 by the gold medal of the Royal Astronomical Society. Honorary membership in many foreign societies was conferred upon him. Colleges and universities have also paid tribute to his genius, and he has received honorary degrees from various institutions, including Yale, Manchester, Oxford and Cambridge.

Just as Prof. Hale's experiments at the Harvard Observatory led to the establishment of the Kenwood Observatory with its more specialised equipment, so his success in the researches carried on in the latter institution led to a desire for a larger observatory with more powerful instruments. The matter was brought to the attention of President Harper of the University of Chicago, who took an active interest in the realization of the plan. Mr Charles T Yerkes agreed to finance the undertaking, and the outcome was the great Yerkes Observatory of the University of Chicago, located at Williams Bay, Wisconsin, 76 miles northwest of Chicago. Ground was broken in 1893, and the observatory was dedicated in October, 1897. Prof. Hale was appointed director of the observatory and professor of astrophysics in the University of Chicago. A complete description of the Yerkes Observatory would be out of place here. It will be sufficient to note that the chief instrument is a refracting telescope with a lens 40 inches in diameter and a focal length of 63 5 feet, the largest telescope of its kind in the world. There are various other telescopes designed for special purposes and a complete equipment of accessories. The observatory and its equipment cost approximately $365,000.

The chief aim of the Yerkes Observatory was a continuation on a much more elaborate scale of the work so successfully begun at the Kenwood Observatory, but the program as announced by Prof. Hale included, in addition to the various classes of solar work, micrometrical observations of double stars, planets, satellites, nebulæ, comets, etc., stellar parallax work, photographic studies of stellar spectra, including determinations of motion in the line of sight; photometric observations, and various physical researches in the laboratories. In order to carry out all of these researches a large staff was required, and Prof. Hale was fortunate in securing such men as Burnham, Barnard, Frost, Wadsworth, Ritchey, Ellerman, Adams, Barrett, Parkhurst and Fox.

For ten years Prof. Hale served as director of the Yerkes Observatory, and during that time the institution assumed a position among the foremost observatories of the world. In 1903 a combination of circumstances including the completion of the five-foot mirror for a reflecting telescope, the gift of Prof. Hale's father; the desire to experiment under the very best conditions with new types of apparatus for solar observations, and the rigorous winters of Williams Bay, led to the decision to establish a branch observatory where the climatic conditions were most favorable. The summit of Mount Wilson near Pasadena, California, was finally selected as the site of the new station. For some months observations were made with instruments borrowed from the Yerkes Observatory, then the Carnegie Institution, devoted exclusively to the furtherance of research, agreed to finance the undertaking, and with the cordial co-operation of the University of Chicago the new observatory severed its connection with the Yerkes Observatory, and in 1904 Prof. Hale became director of the Mount Wilson Solar Observatory of the Carnegie Institution of Washington. For the third time Prof. Hale had the privilege of planning and equipping an observatory.

In many respects the Mount Wilson Observatory is unique. It has no great building like the Yerkes Observatory, nor does it possess any large refracting telescope. Its instrumental equipment includes the Snow reflecting telescope with a mirror of 24 inches aperture and 60 feet focal length, mounted horizontally; a refracting telescope of 12 inches aperture and 60 feet focal length mounted vertically, a refracting telescope of 12 inches aperture and 150 feet focal length, mounted vertically, a reflecting telescope of 60 inches aperture and 75 feet focal length, mounted equatorially, and in course of construction, a reflecting telescope of 100 inches aperture. The first three instruments are fixed in position, the light of the sun being reflected into them by a combination of mirrors. These three are designed exclusively for solar investigations and are fully equipped with such accessories as spectrographs and spectrohelioscopes. These instruments are all mounted on the summit of Mount Wilson. In the city of Pasadena the observatory has a physical laboratory, a building with offices and computing rooms, and another containing machine, instrument, and optical shops.

Here again a large staff is necessary. In addition to Prof. Hale this includes at present Messrs. Adams, Ellerman and Ritchey, formerly of the Yerkes Observatory staff and also Messrs. St. John, Seares, Fath, King, Pease, Babcock and several assistants, computers and machinists.

Of the many achievements and discoveries of Prof. Hale and his colleagues at the Mount Wilson Observatory, a few only will be mentioned, viz.: Investigation with the spectrohelioscope of hydrogen and calcium flocculi on the sun, including structure at different levels and relationship to spots, determination of the law of solar rotation (a) by the motions of the hydrogen and calcium flocculi, (b) by the

(Continued on page 37.)

How to Find Your Way in the Air

Aeronautical Signals; Aeronautic Charts; Steering by Compass

THE rapid progress of aviation and aeronautics obviously demands the development of a system of signals which will enable pilots to find their way in the air and will also indicate convenient landing places, atmospheric conditions, etc Some of the most important events of the year are long cross-country flights Racing in a small closed circuit will gradualy be abandoned The establishment of regular lines of airship transit, as proposed by Count Zeppelin, and the success of aerial touring in general, also depend on the invention of such a system of signals

One proposed method involves the construction of special aeronautical charts, another requires merely the establishment of easily visible signals by which the pilot can find his position on the very accurate ordnance maps which are commonly used as standard maps in France and other European countries In the French system the country is divided into 258 districts, each of which extends about 38 miles east and west and 24 miles north and south, and is represented by a numbered section of the map

According to one proposed system of signals, a large rectangle having the proportions of the corresponding map section and in the correct relative position to the points of the compass, will be marked out on the roof of a balloon shed or other building, or on the ground (Fig 10) The rectangle is marked with the number of the section, and the exact position of the locality in the section is indicated by a conspicuous mark For example, the towns of Beauvais, in section 32, and Nantes in section 117, would be indicated as is shown in Fig 10b A glance at any one of these signals near which he passes will show the pilot his exact place on the map, so that he need not be long lost or go far astray if the signals are sufficiently numerous A predetermined course can be followed without carrying a set of maps It is necessary only to draw, on a small card, a rough outline of the sections crossed by the course and adjacent thereto, to mark each section with its proper number, to mark the positions of the starting and destination points, and to connect these points by a straight line A diagram for a flight from Orleans to Mourmelon is shown in Fig 10b It will be observed that the straight course crosses the northwestern part of section 81. Hence, if the aviator comes to the signal shown in the lowermost portion of Fig. 10b, which indicates a point in the southwestern part of section 81, he knows that he has deviated toward the right hand. The map is required only for the purpose of selecting a good landing place, if the goal is a large town

If the signals are composed of white lines on a black background, or conversely, they need not be very large in order to be visible at a considerable distance A rectangle 12 feet broad and 20 feet long, with lines 20 inches wide and figures 6 feet in height (in actual use at Mourmelon) is easily seen from a distance of one mile and an elevation of 600 feet.

In another system, indorsed by the French National Aerial League, each signal will consist of two numbers, indicating the distance in kilometers north or south, and east or west, of Paris. These signals can also be used in combination with the ordnance maps.

The lines, figures and backgrounds may be painted, or composed of colored tiles, etc Figures composed of silvered glass balls have been employed in experiments at the Eiffel Tower (Figs. 3 and 4).

A person possessing good sight can distinguish parallel lines, properly illuminated, when each line and space has an angular breadth of 1 minute, and can recognize Roman capital letters which subtend an angle of 5 minutes. Hence the letters and figures of signals for the use of aviators flying 1,000 feet above ground should be at least 16 or 18 inches high, and should be composed of lines at least 3⅕ inches broad. These, however, are lower limits, which hold only for motionless, attentive and keen-sighted observers. The aviator's acuteness of vision, like that of most persons, may be somewhat impaired, and if he is alone his attention is distracted by the control of his machine, while even a separate observer finds it difficult to recognise objects which he passes at a speed of 50 miles per hour, or 75 feet per second. Hence the letters and figures should be from 3 to 5 feet high, and their lines from 7 to 12 inches broad. The "antique" capital letters and Arabic numerals adopted for oculists' use by the international ophthalmological congress of Naples in 1909, are the best for aeronautical signals. The more easily recognizable letters, such as A, E, V, should be preferred to the less easily recognizable, such as S, Z, B, R, and the employment of similar letters (M and N, or B and R), as well as the arrangement of letters and figures in one line should be avoided. Although vision is more acute in the open air at noon in clear weather than in an oculist's examining room, it must be remembered that only one day in three is perfectly clear, that aviators prefer the relatively calm morning and evening hours, when mists are frequent and sunlight is less intense, and that the air above large cities is usually laden with dust and smoke. These con-

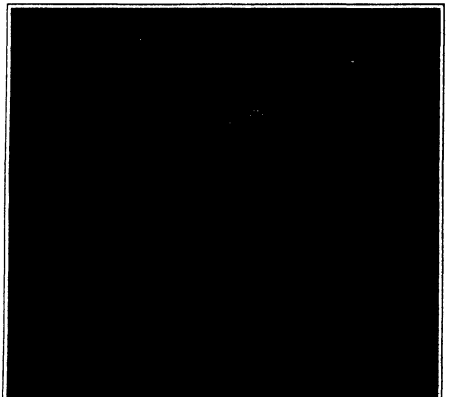

Fig. 3.—An air beacon.

CHARTING THE INVISIBLE OCEAN OF AIR

dictate that the choice of colors used in signals to black and white, or very dark and very light tints. As four or five men in a hundred are more or less colorblind, colored signals, which have caused many accidents on railways and in navigation, should be rejected.

In Germany, it has been suggested to divide the country into districts, and to designate each district by a number and a letter, which would be suitably inscribed on roofs or on signs suspended from captive balloons.

For the guidance of aviators and aeronauts at night a German inventor has devised a translucent red balloon about 8 feet in diameter, containing an electric light of 100 candles or more, and moored by means of an electric cable (Fig. 5). These balloons are easily distinguished from other lights, and from stars, and can be seen from a great distance. Some are already used near Berlin for guiding the nocturnal flights of an advertising airship. They may be employed as captive balloons for marking the positions of airship stations, sheds and landing places, and to indicate the proximity of the sea or other source of danger. They may also be equipped with accumulators and employed as pilot balloons, to indicate the direction and velocity of the wind before starting on a nocturnal flight. In foggy weather, the signal balloon may carry an automatic electric fog-signaling device by which a bell on the ground is rung when the balloon emerges from the bank of fog. These devices are patented and controlled by the Aix-la-Chapelle company.

A signal of a type which is already used to some extent in Belgium is shown in Fig. 6. It consists of a white cross of stone or wood, placed horizontally on the ground and inscribed in large black letters with the name of the place. The pointed top of the cross is directed northward, and supplementary arms indicate by their positions and inscriptions the distances and directions of landing places, shelters, forests, bodies of water, etc.

While aviators and aeronauts have been discussing the merits and demerits of various systems of marking places with signals that he who flies may read, the French War Department has commenced the construction of a map designed especially for use in aerial navigation. The need of such a map was felt keenly during the maneuvers in Picardy, where the pilots of the military airships were compelled to rely on the compass and the regular ordnance maps. The compass is of little utility except in long flights, and even then the lateral drift of the vessel makes it almost impossible for the pilot to keep his bearings, particularly if the view of the land is interrupted by fog. The ordnance maps are very accurate, but they are overloaded with details which only confuse the aerial pilot, who requires only a few conspicuous points of reference, which can be seen and recognized from a considerable distance. These points, as a rule, possess little military importance, and are, therefore, not very conspicuous in the ordnance maps.

The need of special aeronautic maps having been demonstrated by the first official experiments in military aviation, Commandant Pollachi, of the Geographical Service of the Army, last September, undertook the task of preparing such maps, with the aid of expert assistants, excellent equipment, and full and accurate information at the command of the French Geographical Service.

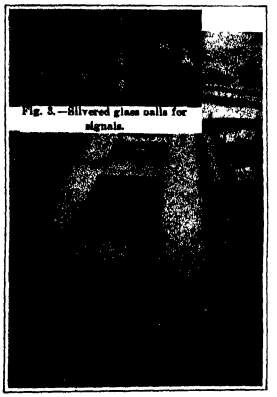

Fig. 3.—Silvered glass balls for signals.

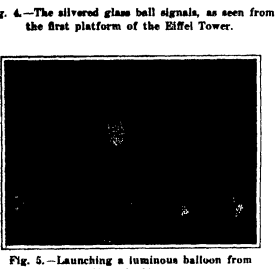

Fig. 4.—The silvered glass ball signals, as seen from the first platform of the Eiffel Tower.

Fig. 5.—Launching a luminous balloon from Aix-la-Chapelle Observatory.

The German general staff had already issued some special aeronautical maps, but, in Commandant Pollachi's opinion, the German maps are overloaded with detail and are drawn on too small a scale (1 to 300,000), and had consequently proved unsatisfactory in the German maneuvers of last year. Profiting by these mistakes, Commandant Pollachi adopted a scale of 1 to 200,000, which permits the introduction of all data useful to aerial navigators, and yet allows a territory measuring 50 by 80 miles to be included in a map measuring 16 by 26 inches.

The first map is already completed, and a portion of it is reproduced in Fig. 7. It is free from all useless and confusing detail, and represents the actual appearance of the country as seen by aviators, as closely as possible, so that it resembles a sort of conventionalized photograph rather than an ordinary topographic map. For example, the highways, which appear to the aviator as long white ribbons, are represented by unprinted strips of fine white paper on the map, bordered by black lines. The general ochre tint of the map resembles that of the ground. Cities, towns and villages are not indicated by the conventional little circles, but are represented by red hatchings of the exact shapes and relative sizes of the real communities. Cathedrals and large churches are indicated by black silhouettes of their main façades, so that they can be recognized at a glance. Solitary trees at cross-roads, windmills, factories, large mansions, monuments and other conspicuous features of the landscape are similarly represented by appropriate and easily recognized figures. Streams, canals, lakes and ponds are printed in blue, and marshes are indicated by blue hatchings, while forests and groves are shown in flat tints of green. Red tints are employed to mark places to be avoided, fine cross-hatching being used for cities and towns, and short, heavy lines, vertical and parallel, for telegraph and telephone lines, vineyards, orchards, quarries, etc. Fortifications are indicated by polygonal scarlet contours, and high voltage electric wires by barbed red lines.

Aviation parks and other favorable landing places are shown in white, and the presence of an airship or aeroplane shed is indicated by a red silhouette of an airship or by that of a rudimentary shed, respectively. The few places where hydrogen can be obtained are indicated by circles.

Railways are indicated by black lines and railway stations by offsets to the lines. Elevations and depressions of the ground are represented directly by shading in bistre and indirectly by numbers indicating altitudes. The mean magnetic deviation of the region is marked in degrees and minutes, and also indicated by an arrow, in the margin of the map.

In Germany a few aeronautical maps have been made

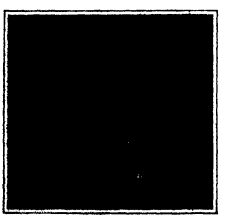

Fig. 6.—The Belgian Cross signal. The point of the arrow is directed northward.

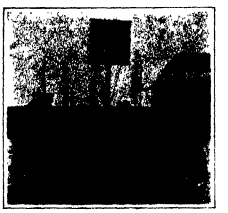

Fig. 9.—Figure-signals by which Farman was kept informed of the distance traversed by him in competing for the Michelin Prize.

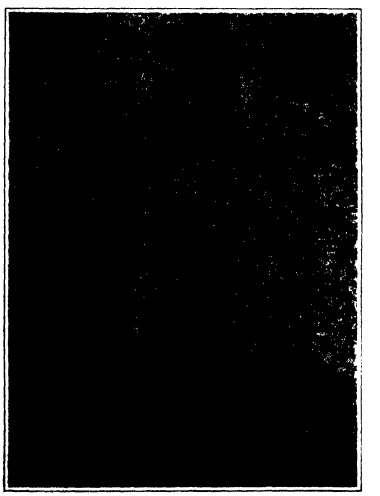

Fig. 8.—German aeronautical map.

THE EARTH FROM THE AIRMAN'S POINT OF VIEW.

by special printings of the maps constructed by the Royal Prussian Land Survey, and it is planned to extend the system over the whole country The scale is 1 to 300,000, and the elevation of the land is indicated by the ground tint of each part of the map, according to the following scheme

Elevation in Meters	Color.
0— 250	white
250— 500	orange yellow
500— 750	raw sienna
750—1,000	burnt sienna
1,000—1,500	lilac gray
1,500—2,000	dark lilac gray
2,000—2,500	dark violet
2,500—3,000	light violet
Above 3,000	white

Contour lines of three types, continuous, interrupted and dotted, printed in sepia, are also used All information which is needed by aviators and aeronauts and not contained in the ordinary Land Survey maps is printed in red, appropriate symbols being employed to designate various objects

Albert Senoucque who was a passenger and observer on the Maurice Farman biplane, with which Eugene Renaux won the Michelin Grand Prix by a flight from Paris to the Puy de Dôme, on March 7th, regards a compass as absolutely indispensable for long flights and says that Renaux steered entirely by the compass during the first sixty-five miles of this journey, which began at 8 50 A. M., when even the river Seine was not discernible at any great distance The compass, of course, should be compensated for the influ-

Fig. 10a.—The roof of one of the military hangars of Camp de Chalons, on which an aeroplane signal is painted.

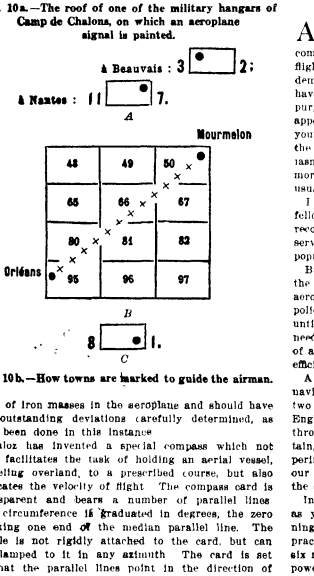

Fig. 10b.—How towns are marked to guide the airman.

ence of iron masses in the aeroplane and should have its outstanding deviations carefully determined, as had been done in this instance

Daloz has invented a special compass which not only facilitates the task of holding an aerial vessel, traveling overland, to a prescribed course, but also indicates the velocity of flight The compass card is transparent and bears a number of parallel lines The circumference is graduated in degrees, the zero marking one end of the median parallel line. The needle is not rigidly attached to the card, but can be clamped to it for any azimuth The card is set so that the parallel lines point in the direction of the prescribed course and the vessel is so steered that the image of the landscape thrown on the transparent card by a lens beneath, moves across the card in the direction of these parallel lines The velocity is determined by means of two lines which intersect these parallels at right angles. From the time which a conspicuous point in the image of the landscape occupies in passing from one of these lines to the other, in connection with the height of the vessel above the ground, as determined by the barometer, the speed of the vessel is easily computed, for the distance between the lines corresponds, in the image, to a real distance of 100 meters, when the instrument is 100 meters above the ground

Mr A G. Marquis, of Rochester, N. Y., has invented a compass with a south-pointing needle and a card which is attached to the frame instead of to the needle, and is marked with the points of the compass in reversed order. When the needle and card are viewed by reflection in a mirror inclined 45 degrees to their plane, the card appears to remain stationary and the needle appears to point in the direction in which the vessel is moving. (SCIENTIFIC AMERICAN, March 4th, 1911.) The oscillations of a compass used in aviation should be deadened by flotation or partial immersion in a liquid, or otherwise, and it is also desirable to protect the instrument from the vibrations of the motor. One aviator uses a compass floating on oil in a vessel which is packed loosely in horsehair

Two beacons have been installed at Spandau, near Berlin, for the guidance of aeronauts and aviators at night One of these beacons is a revolving light provided with a Fresnel spherical lens of 7½ inches focal length surrounded by catadioptric rings, of the type commonly employed in lighthouses The rays which are emitted directly and obliquely downward are brought above the horizon by a reflector and a series of prisms The illuminant is acetylene, obtained from the steel cylinders in which it is sold in condensed form The light is revolved by a turbine operated by the pressure of the acetylene, which passes through the turbine on its way to the burner. The consumption of acetylene is about 8 gallons per hour, and the range of the light is about 10 miles. The range can be doubled by substituting an electric arc and a lens of 12 inches focal length

The smaller beacon is illuminated by 30 incandescent electric lamps of 50 candle-power each, arranged in six circuits, each of which consumes 6 amperes of current. A triphase current of 220 volts is employed The light is stationary but intermittent, the circuit being made and broken by an automatic interrupter at intervals of two seconds. The range of the light is about 1,600 feet.

Naval Aviation

By Capt. W. Irving Chambers, U. S. N.

A SHORT time ago, when flights were made in perfect weather only, the navy regarded aviation with complacency Now that the greater possibilities of flight under average weather conditions have been demonstrated, a majority of our officers are eager to have a hand in the development of aviation for naval purposes, and the fascination of aerial navigation now appeals so forcibly to the spirit of daring in our young officers and men, that our chief difficulty in the future may possibly be so to temper their enthusiasm for flying as to insure the performance of other more necessary and more important duties with the usual degree of efficiency

I have not the least doubt that these fine young fellows would soon be capturing altitude and other records if allowed to do so, and that to advocate conservatism in aviation now, in the face of its present popularity, will seem almost heretical to them

But a certain amount of conservatism, at least in the naval branch of aviation, is imperative, and, as aeroplanes are quickly made, it seems to be sound policy for the navy to make haste yet a little slowly until the machines are better adapted to our special needs or, at least, until we have a sufficient number of aviators trained to use them and to measure their efficiency under service conditions.

A conservative policy is evidently that of foreign navies also, but it is known that France has already two naval aviators and one naval aeroplane, that the English navy has two naval officers under instruction through the courtesy of the Aero Club of Great Britain, and that Italy, inspired by some aeroplane experiments recently made here, in conjunction with our ships, is about to develop a suitable machine of the class that we have already evolved in this country

In fact, although the United States Navy does not as yet actually own an aeroplane, our small beginnings in the development of naval aviation, or the practical efforts that we have made within the last six months have attracted the attention of other naval powers, and we will doubtless soon learn of great advances in the improvement of aeroplanes for naval use generally.

It was only last summer that demonstrations of air flight in this country made it seem probable that aeroplanes could be used from a ship. At that time the principal factor in the general development of aviation seemed to be the stimulus afforded to aviators by substantial money rewards for exhibition flights, and Mr Eugene Ely deserves special credit for cheerfully and enthusiastically entering into the spirit of naval aviation without the prospect of any reward whatever.

Mr Ely may be regarded as a pioneer in this branch, although it should be recorded that he might not have been able to attempt his brilliant work under the auspices of any other than the liberal, yet safe, management of Mr. Glenn Curtiss

It was fortunate for us that one school of aviators was ready and eager to co-operate with the navy; for this connection with the Curtiss school led to a series of progressive experiments that have resulted in the production of a naval aeroplane that is almost perfect.

With this machine Mr. Curtiss is able to arise from or alight on either land or water. He can land on water that is comparatively rough. His "Triad" can be hoisted in and out like a ship's boat and, in accordance with plans already perfected by Mr. Curtiss, we will probably soon be able to launch this machine from shipboard without the necessity for any special platform or the provision of any extra gear that may not be rigged or unrigged in a few minutes.

In my opinion, Mr. Curtiss has recently done more for the development of naval aviation than any other man in the world and he deserves special honor for his liberality and foresight

The usual policy of aeroplane builders is to make the training of military aviators contingent upon the sale of their machines but Mr. Curtiss early adopted the policy of offering to instruct officers of the army and navy in aviation unconditionally, and it is due to this liberality that the navy is ready, now, to train its own aviators, although the money appropriated for independent work in aviation will not be available until the first of July.

The Wright brothers, of whose work the country is justly proud, have also offered to train a naval aviator, and we anticipate the early inauguration of a systematic course of instruction in aviation, entirely under the auspices of the navy, at our own aerodromes, which for obvious reasons it is desirable to have so located as to be accessible to naval vessels.

I regard the development of the naval aeroplanes, or hydro-aeroplanes (the Curtiss type of which has been named the "Triad" from its triple power to function on any of the three elements, air, land or water) as marking an important epoch in aerial navigation

If ever trans-oceanic flight by aeroplanes is accomplished, I presume it will be due to the further development of this class of machine. By its use aerial navigation becomes a matter of comparative safety and a means of delightful pleasure trips and sporting events over water

There is now and always will be sufficient talent in the navy to build its own aeroplanes as well as to operate them and to keep them in the van of progressive aerial architecture. But it is a well known policy of the Department to encourage private industries in the development of war material and, as this policy will doubtless prevail for some time with respect to aeroplanes, I see no good reason for the navy to attempt now to build its own aerial machines It is hoped, however, that this policy will not prevent the navy from making its own laboratory experiments, conducting its own scientific investigation of the problems of aerial naval architecture and engineering and establishing a sound system of standard tests for workmanship. It is also hoped that this policy will not prevent the navy from eventually embodying, in its standard machines, the best points of all makes that are specially suited for naval purposes

From my point of view the principal problem in future flight is the improvement of the motive power. It is the most important because most difficult. Of course, there will be great improvements in the details of shapes and materials and in the assemblage of various other accessories, but we would have been flying fifteen years ago if we could have commanded then the same degrees of efficiency and reliability of the motive power that are at our command to-day. It seems to me, therefore, that there should be some recognized and authoritative government testing for comparing stationary engines and propellers in order to make effective progress in their development. Suitable facilities for this work already exist in the navy. The motors and propellers for future naval aeroplanes will doubtless be thoroughly tested and compared, both in the shop and during flight, at the Engineering Experiment Station at Annapolis and at the aerodrome in that vicinity. In this way the navy may be able to assist in the desired general development.

As for laboratory work connected with the test of models and the materials that enter into the architecture of aeroplanes, the government model plant at the navy yard, Washington, is already well equipped for prosecuting scientific investigation in this direction. There we have suitable delicate recording instruments, a corps of expert woodworkers or model makers and draftsmen under the direction of mathematical experts, and all under the disciplined organization of the Navy Department, ready to undertake the work almost immediately.

I anticipate that, by the introduction of aviation in the navy, we will be able to develop substantial improvements in certain necessary instruments such as the aeroplane compass, for example, and then we

will be able to add something of value to the science of meteorology. Those of us who were brought up in sailing ships realize that our dependence on the wind and weather sharpened our weather instincts. Aerial navigation will doubtless develop in our future naval airmen a yet keener appreciation of weather indications, through their greater dependence on them, and the meteorological observations of these men will doubtless be recorded systematically.

Advanced Study in Electrical Engineering at the Massachusetts Institute of Technology

THE year just completed at the Massachusetts Institute of Technology has found the graduate study which is provided in electrical engineering with an increasing number of students. Prof. Jackson's lectures on the Organization and Administration of Public Service Companies were attended by a class of twelve graduate students and Prof. Pender's lectures on Advanced Alternating Currents and the Transmission of Power were attended by an even larger number of graduate students. Prof. Wickenden's advanced course in the Design of Central Stations and Distribution Systems has also been in demand.

Besides graduating the largest class from the undergraduate course which the Institute of Technology has heretofore graduated in electrical engineering, one degree of Doctor of Engineering and four degrees of Master of Science were conferred on men taking their major work in electrical engineering.

The applicants for permission to become candidates for advanced degrees in electrical engineering are already more numerous than they were last year, and particularly is this true in respect to graduate students who intend to study the problems of electric railroads, electric transmission of power and the organization and management of public service companies.

The Electrical Engineering Department of the Institute of Technology received an appropriation of $3,000 from the Edison Electric Illuminating Company of Boston to be used in an investigation of the relative operating reliability and cost of electric trucks, gasoline trucks and horse trucking, for the purpose of determining to what degree electric trucks are adapted to compete with gas and horse trucks in the city of Boston. This investigation will cover the cost of delivery of goods in the different ways. It will include all questions which concern electric trucks, including the influence of the different kinds of city pavements on cost of delivering goods, and the effects of different routings of the vehicles. The investigation will be partly theoretical but it will be planned to determine practically what it ordinarily costs to deliver goods under city conditions. This part of the investigation will be accompanied by actual observations extended over a period of many months. At least a year will be occupied in this work and Mr. H. F. Thomson has been appointed Research Associate to carry on the work under the direction of Prof. Pender.

The Current Supplement

CITY life presents pressing and peculiar biological problems. One of the most important is the removing of the city's wastes. By the modern methods of sanitary science, these wastes can be purified and rendered harmless. It is with such methods of protecting the purity of inland and seaboard waters that the opening article of the current SUPPLEMENT, No. 1853, deals.—Prof. Henry S. Jacoby, of Cornell University, writes of recent bridge construction in America.—Dr. L. A. Bauer continues his discussion of Ocean Magnetic Work.—Electric energy is sold to consumers either by contract or at a rate proportionate to the current consumed. In the latter case the current is measured by meters. The various meters employed are described and illustrated.—The fifth of Sir J. J. Thomson's Royal Institution lectures on Radiant Energy and Matter is presented.—Major George D. Squier's paper on Multiplex Telephony and Telegraphy, by Electric Waves Guided by Wires, passes to its second installment.

The Microphone and Hidden Water

THE French inventor Dienert has contrived an application of the microphone to the discovery of underground water. One end of a tube is inserted in the ground, the upper end being attached to the microphone. The sounds of flowing or dropping water are conveyed to the ear from great depths.

In the Marne valley two springs were discovered with this apparatus at a depth of about fifty feet below the surface of the ground. It is believed that the apparatus will be of great service in mining operations, both for indicating the location of concealed springs and for communicating with imprisoned miners.

Correspondence

The Forthcoming Merchant Marine Number

To the Editor of the SCIENTIFIC AMERICAN:

One of the most noteworthy announcements made recently in your paper is the one telling its readers of the forthcoming (July 15th next) issue devoted to the "American Merchant Marine."

When I read this, a thrill goes through my heart; I feel a disgrace, a humiliation, a sense of shame, never felt before. When I was a boy, in Missouri, *some great statesmen* told us in school, out of school, and in the press, how the American clipperships were once seen on every sheet of water of the earth, while now we are suffering as a nation after the civil war, but every American heart should hope *that the future would remedy all this.*

Most of these men, as I now realize, were the old school protectionists, who delighted to believe their own stories and who were then, as their followers are now, disciples of Baron Munchausen.

Yes, Mr. Editor! your July 15th number should prove an awakening, not only among the scientific men of the country, but among all true Americans.

Will this number reveal the actual facts? Or will the facts be colored through Pennsylvania glasses? I hope not! Mr. Munn always stood for the truth and nothing but the truth, such as I have known him for forty-six years. It is the real mission of the SCIENTIFIC AMERICAN to smash the system which caused the destruction of our merchant marine. Every schoolboy, every citizen should learn to detect the fallacies which have been saddled upon this great nation in connection with the merchant marine.

I hope July 15th will be a red-letter day in the history of the American nation. We shall see!

MAX JAGERHUBER.

Turner, Orange County, New York.

Aeroplane Stability

To the Editor of the SCIENTIFIC AMERICAN:

I anxiously looked forward to the publication of your May 13th or "Aviation Number," and have read your admirable production with great pleasure. Being in the profession of civil engineering, and having had the privilege of lecturing on "Mechanical Flight" at numerous occasions, dating from 1904 to the present year, I have watched closely all articles that deal with the stability and adaptability of the flying machine, as these have been the principal lines of my studies.

Your editorial rightly mentions that the most important element in the flying machine is stability, with the conclusion that we shall ultimately come to a type of a machine which possesses inherent stability independent of devices requiring equilibristic skill of the operator.

Particular attention is given to the late Octave Chanute, his constant endeavors and his advocacy of automatic stability, but to my knowledge he never even offered a theoretical solution for stability.

In Mr. Marius C. Krarup's article, he refers correctly to the present flying machine as "in part a flying machine, and in part a death trap," and says that "It is without the addition of a single new fundamental idea to supplement or correct its original design." He asks, "What does the engineer say, the man whose profession it is to compare the creations of inventive genius with the data of applied science?" He further states, "Suppose we recommend that inventors work a little harder, and invite imitators to retire from their pernicious activity."

In Mr. Marius C. Krarup's article, he refers correctly to "Stability of the Flying Machine," he says that "the common dihedral angle of the two halves of the main planes to each other, and of the main planes to the keel or tail, give a measure of automatic stability that is now widely understood."

Using the above extracts for the basis of this letter, as an engineer I desire to strongly advocate the necessity of serious study by the inventor and engineer for the accomplishment of stability and adaptability of the flying machine, if the universal use of the same is desired. I agree thoroughly with your statements that it is time to stop imitations, and to work on lines that are founded on better engineering principles.

In the first place, the construction of the machine itself undoubtedly can be greatly improved, by following the well-known forms of truss construction, whereby diverging struts should supplement vertical struts as in the present machine, thereby doing away with the cross chords that tie the present structure together, and in a measure hold their separate parts in rigid relationship to each other. The modern tubular steel is admirably adapted for the construction of the flying machine, and to my mind may be used to the exclusion of wooden braces, with their weak joints and connections.

My studies on mechanical flight have led me to design a machine, whereby automatic stability is theoretically obtained by constructing the wings of either side as separate structures, and pivoting them on the central longitudinal line. The wings of the machine during propelled flight would be mechanically held in a horizontal position as with the present machine, having a very slight, if any dihedral angle, but in case of loss of forward propelled motion or stability, the wings would be automatically raised, as in natural flight, leaving the weight of the body and central portion of the machine below the upraised sustaining areas. This would bring the machine to earth in an upright position, with retarded motion. This proposition is of the simplest construction, the shaft of the engine, being the pivotal axis of the wings.

Together with this theoretical solution for automatic stability, I have furthermore advocated the necessity of adaptability, whereby a machine may alight and travel on the water as would a motor boat, or alight on and travel over land, as would an automobile. This may be accomplished by simply attaching below the sustaining areas spherical or cylindrical rotating hollow floats, further eased and made buoyant by being encircled with modern pneumatic tires.

In promoting the art of mechanical flight, an engineer or inventor is handicapped in the development of his ideas, unless he is endowed with the necessary finances for constructing the same; and I find that publications, as well as individuals, make it very hard for one to develop meritorious propositions of this kind, by insisting upon the inventor or engineer proving his theories before the necessary financial assistance is given.

In reference to your list of the $1,000,000 in prizes being offered, I find no prize available for the development of stability and adaptability in the flying machine.

A prize of $25,000, to be handled by the SCIENTIFIC AMERICAN, in the development of that part of the art, would do more for the advancement of the flying machine toward universal use than the entire $1,000,000 offered, as recounted in your issue.

In these experiments calling for construction and practical demonstrations of the theoretical propositions a good rule to follow would be that unless the theoretical proposition could be eliminated by the judges handling the fund, it should receive the assistance of the fund in the construction and demonstration of the machine. J. EMERY HARRIMAN, JR., C. E.

Boston, Mass.

Waterspouts in Nantucket Sound

To the Editor of the SCIENTIFIC AMERICAN:

In the current issue of the SCIENTIFIC AMERICAN I read with much interest the article on "Waterspouts." Nantucket whalemen, returning from long voyages, frequently related thrilling experiences with waterspouts in the tropical zone, but it was not until the summer of 1896 that the islanders themselves had the privilege of viewing one of these phenomena, for it is rarely that a waterspout has been seen in northern waters. In fact, the spout which made its appearance in Nantucket Sound in 1896 is said to be the farthest north of any on record.

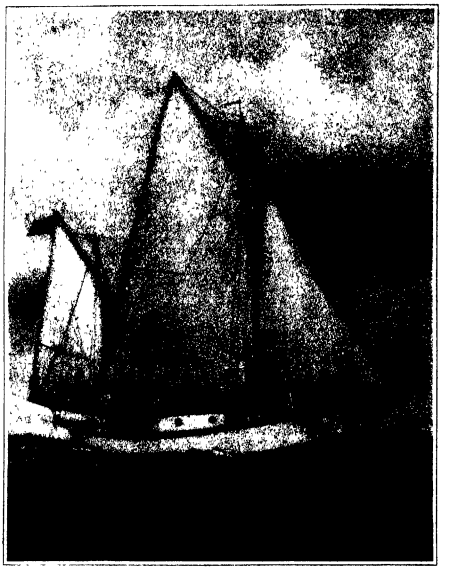
This waterspout appeared in the Sound midway between the islands of Nantucket and Marthas Vineyard, near the Cross Rip lightship, on the afternoon of August 19th, 1896, and I have an excellent photograph of it in my possession. The waterspout accompanied an ordinary thunderstorm, and its progress was noted by the Weather Bureau officials on both islands, the data being on record at the Nantucket station. It first made its appearance at 12 40 P. M., when a tongue shot down from a dense black cloud, rising and falling a number of times. Suddenly a second tongue seemed to leap out of the water and joined that hanging down from the cloud. Twice the waterspout parted, but it joined together again almost instantly, the phenomenon continuing in plain sight of the residents of Nantucket and Marthas Vineyard islands for half an hour.

The spout apparently had no side motion, and it was surrounded by a flat calm, extending over a radius of several miles. A small schooner and a catboat were becalmed within a mile of its base, and those on board the vessels stated that the heat experienced was very oppressive. When the spout broke a cool summer breeze sprung up in the Sound, and the surrounding waters seemed to be full of cross currents and "eddies."

Nantucket sea captains who witnessed this phenomenon stated that the spout was the most pronounced of any they had seen, even in the warmer climes. This is the only time a waterspout is known to have made its appearance in Nantucket Sound.

Nantucket, Mass. HARRY B. TURNER.

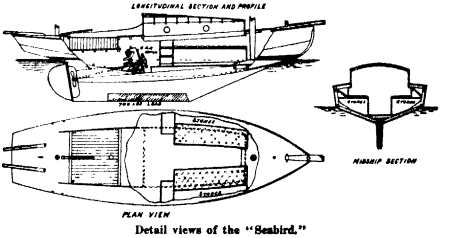
Sailing the Seven Seas in a "Cockleshell"



Two Diminutive Yawls Have Dared the Dangers of the Atlantic and Pacific Oceans

BECAUSE of the daring with which their skippers have sailed them out upon broad and deep waters, and braved the perils of storm, fog, and hidden rocks, two diminutive vessels, the "Seabird" and the "Pandora," are now very much in the public eye.

The first of these craft to attract attention, at least on the Atlantic seaboard of the United States, was the "Seabird," a tight little yawl measuring 25 feet 9 inches in length on deck and eight feet in beam, with a draft of the body of the hull of not much over eighteen inches, and a draft to the bottom of the keel of about three feet. At a normal loading the length of the waterline of the "Seabird" is about twenty feet.

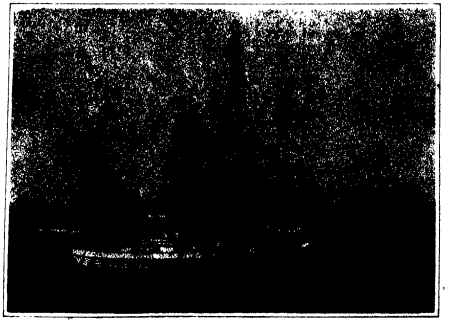


The "Seabird" is one of several designs for small boats which our esteemed contemporary the *Rudder* has published during the past dozen years or so—small, serviceable craft, designed with an eye to comfort, safety, service, ease of construction, and, last but not least, low cost. From these various designs, scores of boats have been built by amateur hands, not merely in the United States, but throughout the world, and, judging from the published stories of their construction and subsequent service, they seem to have been successful and popular. Mr. Thomas Fleming Day, the editor of our esteemed contemporary, the *Rudder*, built a boat from one of these designs as far back as 1904, and named her the "Seabird," and by line and wash drawing our artist has given the SCIENTIFIC AMERICAN readers an opportunity to inspect the craft for themselves. Those of them who are nautically inclined and know something about boats will see that this craft can be easily and cheaply built from such simple materials as can be obtained from the stock of any good lumber yard. In cross section the "Seabird" represents in her underwater body a greatly flattened V, with top sides which rise straight from the bilges, which are at the waterline. The "Seabird" is decked throughout, and the raised cabin roof provides as much head-room as one can reasonably expect in a shallow-bodied boat of this form. There is storage room for spare sails, etc., in the forecastle, and there are two berths in the cabin. The space between the berths and the ship's side and underneath the berths has been utilized for "ship's stores."

The "Seabird" of 1911 differs from the "Seabird" as built in 1904. At that time she had a shallow keel, through which ran a centerboard. As now reconstructed, the centerboard has been taken out and the keel has been lowered until the boat has a normal draft of about three feet. Furthermore, in the bottom of the keel are seven hundred pounds of lead ballast. Another important change has been the installing of a three horsepower motor, which will serve to drive the boat at four knots. Under sail and motor power combined she is expected to make about six knots. The fuel consists of thirty gallons of gasoline and fifty gallons of kerosene. The consumption when power alone is used would be about ten gallons a day; but of course it is intended to use the motor only when there is no wind, or the wind is very light, and, if progress is slow, when the winds are ahead.

Length, 25 feet 9 inches; beam, 8 feet; draft, 3 feet. Carries an auxiliary 3 horse-power motor. Speed, under power, 4 knots; under power and sail, 6 knots.

The yawl "Seabird" in which Editor Day is crossing the Atlantic.



Detail views of the "Seabird."

The "Seabird," it will be observed, is rigged as a yawl, with jib, mainsail, and mizzen. The yawl rig is recognized among yachtsmen and all sailormen as about the most handy and safe for the smaller craft, particularly when they are exposed to heavy weather and sudden squalls. A yawl whose sail plan is well balanced can be sailed under jib and mizzen, or under the mainsail alone. Under storm jib and reefed mizzen, she is a particularly handy craft in quite a strong blow; and if the wind should rise to the strength of a full gale, all sail may be furled, and the vessel handled nicely under a small trysail on the mainmast.

Public interest in the "Seabird" lies in the fact that she is now sailing across the North Atlantic Ocean on a pleasure trip, if you please, to Rome. The crew of the little craft consists of Mr. Day and two men, it being the claim of Mr. Day that there is no greater danger for small craft, if indeed as much, in ocean sailing than there is in sailing within sheltered but crowded waters, such as Long Island Sound. He believes that the best Corinthian sailors are found among those who strike boldly out for deep water and learn to navigate by sextant and compass. It is largely due to his influence that long-distance ocean races now form a regular part of the summer schedule of our yachtsmen, both on the Atlantic and the Pacific. Notable among these are the races to Bermuda and those from this port to Marblehead.

Mr. Day has always been a firm believer in the sea-going qualities of the yawl, and the present cruise from Boston to Rome on the Mediterranean, is proof that he has the courage of his convictions, even though his craft is so small that Hudson's "Halfmoon" could have stowed her on deck, and not have been greatly inconvenienced thereby. The course laid out for the "Seabird"

SAILING THE SEVEN SEAS IN A "COCKLESHELL"

Automobile Novelties

A Motor Car for Assayers; Psychological Tests for Chauffeurs

Searching for Mines in a Motor Car

HEREAFTER it will not be necessary for the prospector to undergo the hardships of the trail, for a Los Angeles mining man and inventor has set the pace for the twentieth century search for mines. Mr. H. W. Larsson, assayer, engineer, and practical prospector, has built an automobile which is fully equipped for desert travel, and which will not only enable him to carry the comforts of civilization with him on his quest for precious ore, but also to test his sample within an hour after he finds a promising lead, thus saving much valuable time.

This highly original combination of motor car, Pullman coach, and assay office was constructed entirely from Mr Larsson's plans, only the wheels being bought in their finished state, and apparently no detail has been overlooked to provide for the comfort of the travelers. There is a reason for this, as Mrs. Larsson is now accompanying her husband through the southwestern desert The housekeeping equipment is exceedingly compact.

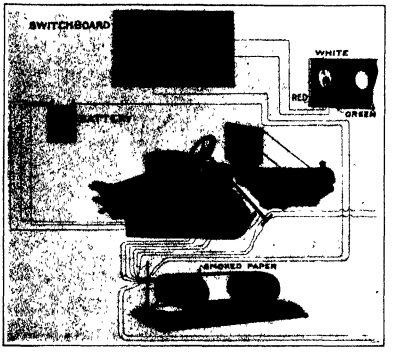
A table folds up against the wall, and when it is let down discloses a small kitchen cabinet and triple cooking outfit, while lockers, china closet, larder, and medicine chest are so arranged as to take up the least possible room Two 20-gallon tanks of water are carried, and that used for drinking purposes runs through chemically cooled pipes and is delivered ice cold The water faucet and glass are conveniently arranged near the driver's seat. This seat, by the way, is reversible, so that at the meal time it can be made to face the dining table instead of the front of the car

The engine is connected with a dynamo which furnishes electric lights for the little home on wheels. Two comfortable berths are arranged so that they can fold up against the wall when they are not in use, and a kind of folding chiffonier is provided for wearing apparel

The automobile is equipped with sliding glass windows and green curtains which insure privacy, while a row of small ventilators extends all the way around the car directly under the roof.

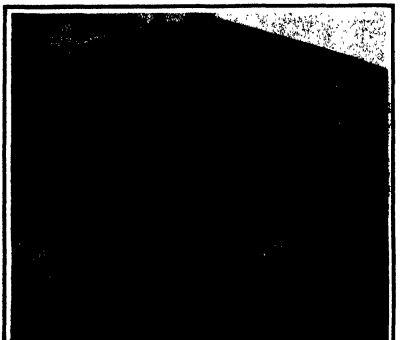
So much for comfort From the utilitarian standpoint, Mr Larsson's plans are no less thorough From his own model was constructed a three-cylinder, two-cycle engine with double friction drive of a proved 33 horse-power This carries the car along at a rate of sixteen miles an hour, which is ample speed for his purpose It also furnishes the power for the electric lighting plant and the ore crusher which grinds his specimens to the fineness of 100 mesh.

The complete ore-testing equipment consists of a rotary flame combination furnace with Cary burner and tank outfit, a Braun pulverizer, and a steel frame Chipmunk crusher.



These are all in miniature size, but of course do the actual work required for the prospector, and in addition to this they can be used to demonstrate the efficiency of the same outfit on a large scale, so that in one sense this up-to-date prospector might be called a traveling salesman for the manufacturers of these machines. This, however, is a side issue, and merely indicates how far the modern prospector has departed from the ways of the former generation of burro packers. Four tanks of gasoline are carried, each of ten-gallon capacity. The general appearance of the car is very attractive without being ornate. Its dimensions are, length, 12½ feet; width, 4½ feet, and height, about 7 feet.

In addition to his mining work, Mr. Larsson intends to do an excellent service to his fellow prospectors and desert travelers in marking the trails to water holes along his route. He will also place guide posts indicating the number of miles from the various camps, and the distance will be accurately determined by his speedometer. The metal guide posts, 250 in number, were supplied gratis by F. W. Braun of Los Angeles, and will do much to mitigate the hardships of the trail.



Psychological Apparatus for Testing Chauffeurs

By Ralph Bergengren

ALTHOUGH no definite relation has yet been established between the operation of statute law and the experimental study of human beings by the psychologists, many experts in both fields are coming more and more to believe that psychology will play an important part in legal procedure during the present century. Practically the psychologist has so far taken no part in legal proceedings But he has invented apparatus that can detect the hidden emotions of a witness far more certainly than any unaided cross-examination and that will force the truth from a suspected criminal, without cruelty if he happens to be innocent and with an absolute precision impossible in the ordinary methods of police interrogation To record and measure the hidden feelings of an individual in regard to any given subject is evidently more reliable a way of getting at facts than to ask him questions without any definite method of determining the truth of his answers Herein, it is argued, lies the future of psychology as a practical first aid to law and order

PSYCHOLOGICAL TEST APPARATUS FOR CHAUFFEURS

REAR OF CAR, WITH ORE CRUSHER IN OPERATION

The latest example of psychological apparatus that might be applied to the routine business of a municipality is a mechanism devised by Mr. Charles Sherwood Rieker, of the Department of Psychology at Harvard University, for the purpose of testing the reaction-time of the man behind the steering wheel of an automobile. A reaction-time, in psychology, is the exact space, measured in fractions of a second, necessary for a given individual to receive a given impression and perform the actions suggested by it. Applied to criminal investigation, for example, the criminal, being asked any question that suggested his crime, would answer that question by an infinitesimal fraction of a second more later than he would answer questions without such connection Whatever his control over his features, he would be unable to prevent this infinitesimal slowing up of the mind when the crime was recalled to him And so when applied to the problem of individual capacity to run a motor car the psychological apparatus gets down to conditions that no amount of verbal examination could possibly arrive at Legal qualifications for handling a motor-driven vehicle vary at present in the different States The severest requirement demands that the applicant for a license shall prove that he has driven such a vehicle at least one hundred miles Among the questions most generally asked of such candidates, three are almost universal Do you habitually use, to excess, intoxicating beverages? Have you any mental or physical incapacity or infirmity which would interfere with your management of an automobile? Have you ever been convicted of any offense against any laws in relation to the use of automobiles on public highways?

One hardly needs be a psychologist to see that neither the mere negative answer to these questions nor the fact of his having driven an automobile over a hundred miles proves that an individual should be trusted to run a motor car Candidates are unlikely to admit, or even believe, that they ever use intoxicating beverages to excess. Physical infirmities that may result in motor accidents may also be entirely unsuspected by their possessor The third question has little bearing on the capacity of the individual to run his car, although it may show his attitude toward the law And the hundred miles over which he has driven a car may easily have been a hundred miles of open country road and no test whatever of what will happen when he meets some sudden emergency in a crowded street The really important question is not what the candidate has done but what he is likely to do under the most sudden and unexpected emergencies No man, unless he has long experience with emergencies, can tell how quickly and efficiently he would be likely to meet a new one But the psychological apparatus devised by Mr Rieker answers this question by bringing the man suddenly face to face with the emergency and measuring the time it will take him to meet it with the various controls of his motor car

The apparatus consists of a device for signaling the emergency and another for recording the reactions of the motorist A dummy motor car is provided with the regulation steering wheel, the side throttle that controls the different speeds, the foot clutch whose release throws the machinery of the car immediately out of gear, and the emergency brake In place of the ordinary wind shield the psychological motor car has an opaque screen with three openings and in front of the screen are three electric bulbs invisible to the chauffeur except when one or the other of them suddenly glares at him through an aperture These bulbs, white, green and red respectively, are so arranged that they may be revolved in front of the openings in the screen by means of an electric push button under the finger of the psychologist conducting the experiment. Outside the car, or in the tonneau of a real automobile, if the tests were being made on the road is a cylinder of smoked paper which revolves steadily and is in contact with the end of a tuning fork and almost in contact with four little metal pointers respectively connected by an open electric circuit with the steering wheel, clutch, throttle, and brake

Pressure on the push button that flashes one or another of the electric bulbs in front of the chauffeur sets the cylinder or time clock in motion, and the tuning fork begins tracing a sharply scolloped line on

Abstracts from Current Periodicals

Phases of Science as Other Editors See Them

The British Naval Airship

At last the British leviathan of the air has emerged from the interior of its hiding place into the full light of day. And it is an immense dirigible, too, indeed the largest in existence. Over 170 yards long, no less than 16 yards in diameter. According to *Flight*: "It has a gas capacity of 700,000 cubic feet, a lift of 21 tons, its engine power is no less than 400-horse power in two equal units formed by Wolseley engines. It can carry twenty-two persons and has cost up to date the sum of $205,000. More than an acre and a half of Continental fabric was employed in the construction of the envelope, and the hydrogen, compressed in cylinders, was brought over from Wolverhampton by the train load at a time.

"During two years this airship has been in course of design and construction, and the lines on which it is built are broadly similar to those of the famous Zeppelin airships that have created so many sensations in Germany. We will at least hope that the English vessel will be more fortunate. Its constructors are the great firm of Vickers, Ltd.

"The characteristic feature of the type to which it belongs is the rigidity of its envelope, which has an interior skeleton framework made of duralumin, the new light aluminium alloy. This framework maintains the shape of an envelope, which is thus not dependent on the gas pressure as it is with airships of the non-rigid type that are intended to be capable of being folded for transport by land.

"Inside the framework of the envelope are seventeen ballons filled with hydrogen, each balloon forming a separate gas-tight chamber of its own, and if deflated by accident would not affect the others. Outside the framework is a covering of fabric, the appearance of which is somewhat distinctive owing to the upper part being silver gray and the lower half yellow in color. The upper part is as fat as possible a non-conductor of heat, and thus minimizes the effect of the sun's rays on the expansion of the gas. The lower part, on the other hand, is a conductor of heat and thus facilitates the proper equalization of temperature between the gas and the atmosphere to be carried on in a normal manner.

"In accord with the most modern theories of streamline form, the envelope is cylindrical in the middle, with tapering extremities. The nose is blunter than the tail. On the tail of the envelope or hull, as it may be termed because of its rigidity, are the directive organs, consisting of four stabilizing fins (two vertical and two horizontal), two sets of quadruplane rudders and two sets of triplane elevators. There is also an elevator under the bows and another rudder right under the stern, these latter being both situated next to the cars. Beneath the hull are two 20-foot cars or boats joined by a gangway. In front the engine drives two four-bladed propellers, carried on outriggers beneath the hull; at the stern there is a single two-bladed propeller.

"Water ballast is employed and the estimated speed of the airship is 30 miles per hour. For mooring purposes the bows of the airship are anchored to a mast rising from a kind of raft, which also carries a great net screen like a sail. The mesh of this screen is sufficiently close to break down the force of the wind without being itself torn away in the process, and the anchorage is such that the airship and its screen can veer round so as to keep head on to the wind. The airship is in charge of Capt. Sueter, who has under him Lieuts. Usborne and Talbot. The present ship to which she is attached is the cruiser 'Hermione.'

"It took 300 bluejackets less than an hour to haul the airship out of her shed and get her safely moored in Cavendish Dock in the early hours of Monday morning, May 22nd. To be precise the performance commenced at ten minutes past four, and was all over long before most people had waked from sleep. One of the most striking sights in connection with the launch was the sudden appearance of sailors on the very top of the envelope, where there is a prepared gangway, and access to which is obtained by means of a rope ladder through the center of the envelope itself."

THE NEWEST OF DIRIGIBLES

Observations on Scientific Management

"MODERN watches are marvels of intricate and perfect construction," says Mr Harrington Emerson, the efficiency engineer, in the *Engineering Magazine*. "Any child can push a stick in the ground and by the position and length of the shadow determine approximately the time. A clepsydra or water clock, an hour glass, physical material leaking away at a uniform rate, was a decided advance at guessing on the time in the dark, or the time for boiling an egg. The early clocks with their pendulum escapements required many months of experimental test before length of pendulum, meshing of wheels, amount of weight, were adjusted to one another. There are as many different kinds of watches and clocks as there are locomotives; but each is perfect with a perfection so great as to be almost inconceivable. The jewelled bearings, the almost microscopic yet mathematically perfectly shaped teeth of the wheels, the hair spring, the balance wheel, each is perfect in itself, perfectly related to the others, until the whole is also perfect. This is not all. Delicate, automatic machines are made which turn out these perfected parts so exactly alike as to be interchangeable. Turret lathes and screw machines, automatic machines in general, were earliest adapted to clock and watch making, and from that extended to larger and heavier parts, often beyond the point of economy; for in watch screws the material, even if of gold, would not amount to very much, the perfection of finish being all important, but as the weight of material grows with the cube of its linear measurement, we cannot afford to make on automatic machines crank pins or even knuckle pins for locomotives, it being too expensive to cut down the solid bar.

"It would take no more thought and work to standardize operations for building a locomotive than for building a watch. The difference is that watches are turned out by the hundred thousands and locomotives only by the thousand; but this difference is not as great as it seems, for a watch movement may average $5 in value and a locomotive $15,000, so that one locomotive corresponds to 3,000 watches, and we have not hesitated to undertake the work of designing each separate locomotive part, we need not fear the labor of standardizing the operation of manufacture for each separate locomotive part.

"Another instance of standardized operation is the printing of a book. The old writers were individualists; there was no standardized operation. Each made not only the size of the letters to suit himself, but also their forms, took pride in not being like other scribes; each spelled the words his own way, each used his stylus or brush as he preferred, preparing his own ink, his own papyrus or parchment. Now we buy half a dozen newspapers a day for a cent each, we buy a dozen magazines a week for 10 cents each, we buy a hundred books a year for a dollar or two each. Scarcely any two books are alike; there is far greater variation than in locomotives or watches; but each book is made up and printed with standardised spelling, standardized lines, standardized pages and standardized signatures; even the book itself approaches a standard in size. The ink is made to suit various fluctuations in the weather, the paper is made to suit the quality of the book in press. While printing is as yet standardized in a rudimentary way only, while it affords a field as large as any manufacturing business in the country, it has nevertheless in certain limited directions standardised operation to an advanced extent.

"In the watch, in the book, we have the standardised operation as to the manner in which it shall be carried out; but there is another element—that of individual skill.

"Two men may both show a model wall of brick, yet one man may have laid 3,000 bricks a day, the other man only 300.

"So true it is that one man and one intellect properly qualified for the particular undertaking is a host in itself and of extraordinary efficiency.' Thus wrote Polybius, 212 B. C., in describing the work of that great engineer Archimedes, who, by his individual genius, flung rocks from catapults at the approaching besieging ships, who constructed cranes that let down grab hooks, lifted the ships out of the water, and turning them over, let them fall to destruction.

"Horses have trotted and trotted well for many centuries, but it remained for Americans to figure out that the value of a minute might be rated at $3,000,000, and that to eliminate the minute, to evolve the mile-in-two-minute horse from the mile-in-three-minute horse would be worth this amount. Prizes were offered to crack trotters for beating their own record, $10,000 for the fifth of a second, and there are 200 fifths in a single minute. It was not only the horse that was developed; it was also the American stop-watch spirit, so that our fire fighters, witness every movement for men and teams has been standardized, are able to charge across the threshold of their fire-house 30 seconds after the gong has sounded.

"At an international contest in Berlin several years ago it took the English team over two minutes and the German team over eight minutes to make a start. This is quite a contrast as compared with the American performance.

"Now aeroplanes have come; and at the international meet in Belmont, true to our national virtues and our national faults, we were prepared to time the flights to the hundredth part of a second, but with a year's warning we had no machines. Wright, with 'to fly' and we lost to the foreigners because we were unprepared."

The Movement of Soil Material by the Wind

UNDER the above title the United States Bureau of Soils has just published, as its Bulletin No. 68, a monograph by E. E. Free, which, including an enormous bibliography of æolian geology by Messrs. Stuntz and Free, comprises 372 octavo pages. This work brings together, correlates and summarizes practically everything known in regard to æolian geology, so far as that subject concerns the student of soils.

While the activity of the wind as a geologic agent has long been fully recognized, its action on the soil has not heretofore been adequately treated as an agronomic problem. It is, however, a most important factor in the complex system of soil movements affecting soil fertility. The soil of any particular farm or field is continually changing under the action of the wind. This action, when moderate, is beneficial to fertility; when excessive, it is one of the serious obstacles to successful agriculture, and must be controlled by various expedients, such as windbreaks, cover crops, rotation schemes, etc. This matter is important not only to the tiller of the soil, but also to the builder of railways and highways, the irrigation engineer, and many others.

Such is the important economic problem that Mr. Free has undertaken to discuss, but he has far exceeded his theme, and has produced a memoir replete with interest to the physical geographer, the geologist, and the meteorologist; for his work is a digest of existing information concerning the solid content of the air; its composition and sources, the mechanism of its transportation; and the many effects of its removal from and deposit upon the earth's surface. The scope of the work may be judged from the following principal headings in the text: Heterogeneity of soils; translocating agents in general, the limitations of water translocation; wind translocation; the mechanics of wind translocation; drifting sands and sand dunes; dust storms and dust falls; the continual drift of soil material with the wind, true atmospheric dust; geologic formations of æolian origin, volcanic dust as soil material, wind transport of vegetable matter; translocation in general, excessive blowing of the soil.

In one respect, in particular, Mr Free has set an admirable example to the writers of scientific monographs. His text is supported at every step by copious and well-nigh exhaustive references to the sources of his information. These references number many thousand; so that under each topic discussed the reader will find a complete bibliography of the same; and the references are repeated in an amplified form, alphabetically arranged by authors, at the end of the book As a contribution to scientific bibliography this work is almost unrivaled among recent official publications; while the text is an invaluable summary of the immense body of literature upon which it is based.

The Prevention of Malaria[1]

AMONG the most striking successes which preventive medicine has achieved in recent years is the very extensive subjugation of malaria as the result of the recognition of a certain breed of mosquitoes as the carriers of the disease The subject, on which there is now considerable literature, has been treated in collective form in a hand book recently published by Prof R. Ross, and reviewed in a late issue of *Science Progress*. The reviewer, E. A. Minchin, says in part:

"Prof. Ronald Ross, poet, mathematician, and apostle of tropical sanitation, gives us in the first half of this book the fruit of twenty years' research and experience with regard to the causation and prevention of a disease which, on his estimate, causes 'between a quarter and a half the total sickness in many tropical countries.' The remainder of the book consists of reports from those who have put Ross's principles and methods into practice in every part of the globe; their results afford a brilliant testimony to the immense value to humanity of the modern discoveries regarding the etiology of malaria, a subject in which Ross himself led the way and broke entirely new ground.

"The aims and objects of this book are essentially practical and utilitarian; it is intended to set forth concisely and in a form popularly intelligible the relevant facts concerning the natural history and causation of malaria, in order to show clearly how the disease may best be prevented and eradicated. It is, in short, a manual of instruction for medical men, sanitary officers and administrators upon whom may fall the task of combating malaria in some part of the globe. For this reason the more purely scientific aspects of the malarial problem, such as the marvellous and complicated life history of the parasite in its two hosts, vertebrate and insect, are dealt with as briefly and simply as possible.

"The malarial theorem, as Ross aptly terms it, may be stated briefly as follows. Malaria in man or animals is a disease caused by a minute parasite which lives and multiplies in the blood, passing its trophic phase within the red blood corpuscles The parasite is propagated from one vertebrate host to another by the agency of certain mosquitoes, which, on sucking the blood of an infected vertebrate, take various stages of the parasite into their stomachs with the blood; one stage of the parasite resists the action of the digestive juices of the mosquito and passes through a sexual process of generation and multiplication within the body of the mosquito, the cycle ending after some days with the production of many thousands of minute germs ('protospores,' Ross) lodged in the salivary glands. If the mosquito then succeeds in biting a vertebrate of the right kind, that is to say, of the kind which is a specific host of the parasite in question, the germs pass down its proboscis and are inoculated into the blood, thus bringing about a fresh infection of the disease Every statement made in the foregoing sentences is based on rigorous experiment or accurate microscopical investigation It only remains to add that the various species of malarial parasites are specific to certain hosts, vertebrate or insect, those of birds, for instance, can only be transmitted by mosquitoes of the subfamily Culicine; those of men only by the subfamily Anophelinæ

"The principles of malarial prevention depend on the facts stated above, their aim is to interrupt the complex chain of circumstances upon which the existence of the parasite depends If the parasite cannot pass from man into the mosquito, or from the mosquito into man, it becomes extinct with the death of its host, if not before Hence there are three general principles of prevention (1) *mosquito-reduction*, that is to say, measures undertaken with the object of destroying mosquitoes or their aquatic larvæ, or of abolishing or reducing the pieces of water suitable for them to breed in; (2) *treatment* of human beings with quinine, either with the object of reducing the cases of sickness, or in order to enable the healthy to resist infection, should they chance to be bitten by an infected mosquito, (3) *protection* of human beings against mosquitoes by various methods, especially by rendering houses proof against these insects Any of these three methods is sufficient to extirpate malaria completely, if carried out thoroughly If, in a given locality, the Anopheline mosquitoes are exterminated, or if there are no infected persons for them to bite, or if they are prevented from biting human beings, the disease cannot continue. But in practice it is always impossible to carry out any of these methods completely and it is necessary to rely upon a combination of the three The best results are always obtained by mosquito-reduction, since it can be effected by administrative regulation, while treatment and protection depend mainly on individual effort—always difficult to control or enforce.

"Such are, very briefly, the main aspects of the problem of preventing or extirpating malaria, but many pages are required to set forth the intricacies and complications of the question

"Turning to the second half of the book, it is impossible to give in a brief space an account of the many anti-malarial campaigns in all parts of the world that are described and reported upon by twenty-one different writers It must suffice to state briefly the results obtained in Ismailia, that most striking example of the practical importance of Ross's researches and of the efficacy of his methods, as set forth by Mr H C Ross

"The town of Ismailia was founded by M de Lesseps, who intended it to be a model city, a thriving port and the headquarters of the Suez Canal Company It progressed rapidly, rising to a population of 10,000, until in 1877 malaria made its appearance, 800 cases being notified in that year. From 1885 to 1902 the number of cases annually was seldom much below 2,000, and in 1891 it rose to over 2,500, more than one-quarter of the whole population In 1902 an anti-malarial campaign was started under the auspices of Prof Ronald Ross, directed chiefly toward the extermination of the mosquitoes. A marsh near the town was drained; pools were filled up and a mosquito brigade was organized consisting of a European foreman and two natives The duty of the brigade was to visit every house once a week, to treat the cesspools with petroleum, in order to kill the mosquito larvæ; to empty all standing vessels or tubs containing water, and to clear all irrigation channels of reeds, so that the water could flow swiftly. Penalties were imposed on the inhabitants if they did not report to the authorities the existence of untreated collections of water. The work cost $10,000 the first year and about $5,000 a year subsequently. For this relatively trifling outlay the most remarkable results were obtained The number of cases of malaria fell at once, in 1903, to 300; in 1904 there were 90 cases, in 1905, 37, since then no fresh cases of malaria contracted in Ismailia have occurred, the disease is stamped out It is necessary, however, to continue the preventive measures, since if the mosquito brigade stops work for a week the mosquitoes return, and there is always the danger, in that case, of a recurrence of the epidemic through infected persons from without coming into the town

"Nothing shows more clearly than the case of Ismailia the possibility of combating malaria effectually in any locality if anti-malarial measures, especially that of mosquito-reduction, be carried out rigorously The failure to obtain similar results by similar methods in other places must be ascribed mainly to the obstacles which stand in the way, of which the chief are ignorance and blind resistance to administrative efforts on the part of the people, or official apathy and parsimony on the part of the government classes." Prof Ross speaks out strongly on these subjects, as he has done frequently before It is to be hoped that this book will be widely circulated among medical men and administrators in the tropics, and that it will lead to a proper understanding of the measures to be taken against one of the greatest obstacles in many lands to civilization and progress

[1] *The Prevention of Malaria.* By Ronald Ross, K.C.B., F.R.S., Major, I.M.S(ret.). With Contributions by Prof. L. O. Howard, Col. W. C. Gorgas, and others. (Illustrations, xx + 660.) (London: John Murray, 1910.)

Visual Sensations from the Alternating Magnetic Field

FOLLOWING on the experiments reported by Prof Silvanus P Thompson, it is interesting to note the further research in this subject pursued by Mr. Knight Dunlap, an account of which appears in a recent issue of *Nature*

"Prof Thompson subjected the head to the influence of an alternating magnetic field, which was obtained by means of a coil of thirty-two turns of stranded copper conductor having an internal diameter of 9 inches and a length of 8 inches The coil was supplied with a current the maximum value of which was 180 amperes at a frequency of fifty cycles per second

"On inserting the head in the coil under these conditions, a flickering light sensation was obtained, the sensation being more clearly defined in the peripheral part of the field of vision

"The object of the further experiments by Mr Dunlap was to ascertain whether or not these sensations were due to idio-retinal light, under the suggestion of the hum of the coil caused by the alternating current.

"A coil was constructed which gave a field of approximately the same density as that obtained by Prof. Thompson, and identical results were observed

"In order to ascertain whether the effects are due to idio-retinal light and suggestion, some experiments were carried out in which suggestion was eliminated to the fullest extent

"In these tests the transformer was placed near the coil, so that the hum of the coil was completely drowned by the noise of the transformer Arrangements were made whereby the current could be switched from the coil on to a resistance, the strength being maintained constant

"The subject's ears were plugged up, and a telephone receiver connected to the transformer was hung on the coil

"Under these conditions it was absolutely impossible to tell by the sound whether the current was on or off the coil, each of the observers was able, however, to identify the flicker with absolute precision when the current was switched on to the coil.

"With a field alternating at a lower (twenty-five cycles per second) frequency, it was found that sensation was much more pronounced and intensely disagreeable, the whole visual field quivering as if illuminated by a rapidly intermittent light

"The effect was at all times very intense when the side of the head was presented to the coil, but on looking into the coil it practically disappears From this Mr. Dunlap infers that the sensation is due to currents induced in the optic pathway, he states that whether these currents excite the occipital cortex directly, or excite the retina primarily is a matter for conjecture, the fact that the flicker is produced by alterations faster than the fastest flicker from normal light stimulation being, it is stated, no evidence for the non-retinal character of the flicker in question

"It is stated that there was no evidence to show that there was a definite arousal of visual sensation by the alternating field, the effect appeared more like an alternate intensification and inhibition of whatever sensory process was already in progress That is to say, the idio-retinal light which is present before the current is turned on is increased and decreased alternately."

[The Editor of Handy Man's Workshop will be glad to receive any suggestions for this department and will pay for them, promptly, if available.]

A Dangerous Muffler

To the Editor of Handy Man's Workshop

IN Handy Man's Workshop of June 10th there is a description of a muffler for gasoline engines, which may work all right and certainly will be a good silencer so far as the noise from the exhaust is concerned, but some day the engine will get to missing fire—they all do it some time—and then the unburned gases will be forced from the engine into the barrels. This may continue for a time and then a weak charge in the engine will be fired and the fire will be communicated to the unburned gas in the exhaust pipe and from that into the barrel and away will go the barrel as if a large charge of powder had been exploded. I have long known of the danger in such cases. Only a few years ago a party had an engine in one of the buildings I now own, and had placed a large box under the flooring into which the exhaust from the engine went, passing thence to the outside. Then the batteries became weak and the engine began missing, and a little later the gas in the box exploded. It tore up about 15 feet square of floor and broke nearly every glass in the lower story of the building, 24 by 60, and did a lot of other damage. It hurt one workman considerably, but did not kill any one, which was considered very lucky.

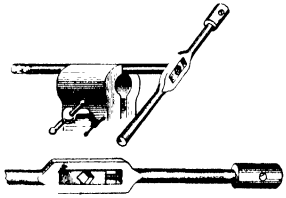
A Good Substitute for a Drill Post

By R. C. D.

THERE are times when one is in a quandary as to the best way of setting up a drill post or "old man," as it is sometimes called. This is particularly true when one has nothing but a curved surface on which to attach the base of the post. To overcome this trouble when holes are to be drilled in cylindrical objects such as metal posts, poles, boilers, etc., one may use a chain attached to a metal plate shaped as shown in the accompanying illustration. This plate has hooks forged or attached to its ends as shown, and to one of these one end of the chain is permanently secured. The other hook is made just large enough for the links of the chain to pass over it freely. In this way the device is made adjustable on objects of various sizes. The method of using the device in connection with a ratchet drill is clearly shown in the illustration.

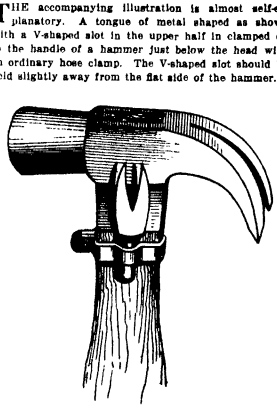


Substitute for a drill post.

Reducing the Size of Tubing

By F. C. I.

IT often becomes necessary to reduce the size of copper tubing so that it will enter a connection which does not admit of being reamed out to a larger size. If the tubing is filed down to fit it weakens the connection. The tubing is easily and neatly reduced by means of a tap wrench, which is placed over the end and tightened as it is rotated. The tap wrench should be tightened gradually, or it will crimp the tubing.



Reducing a tube with a tap wrench.

Nail-holder for Claw-hammers

By W. J. C.

THE accompanying illustration is almost self-explanatory. A tongue of metal shaped as shown with a V-shaped slot in the upper half in clamped on to the handle of a hammer just below the head with an ordinary hose clamp. The V-shaped slot should be held slightly away from the flat side of the hammer.

Nail-holder for a hammer.

When it is desired to drive a nail in a location where both hands can not reach, for instance, above the head or to the right or left, when standing on a ladder, the nail is placed in the slot, with the head against the hammer head and the point extending to the side. A sharp blow starts the nail, and on withdrawing the hammer, the nail can be driven home.

Centering and Reboring Engine Cylinders in a Lathe

By H. C. Urbaner

TAKING for granted that our friend wishes to rebore cylinders in an ordinary lathe, I think he will find the following simple method very helpful.

First, fit a hardwood block (2 by 4 preferred) into each end of the cylinder so that it will hold a rigid position. Now take a pair of hermaphrodite dividers and accurately fix a center into these blocks. Then with a three-quarter inch drill, or an inch drill, bore holes through these blocks at the centers described so that they will be in line with each other. Now fit a rod through these blocks so that it will extend far enough out of each end of the cylinder to meet the lathe centers without interference of projections of the cylinder. Here I may state that the centered blocks alone will be sufficient on a cylinder having both ends fitted with a head.

Next lay the cylinder on the slide rest and with hardwood blocks. If iron blocks are not available, block it up until the centers previously made in the rod will be accurately in line with the lathe centers, when the cylinder is lightly bolted and clamped to the slide rest. This is the all-important step of the entire process, and must be done accurately with whatever material there is at hand.

Now for a boring bar. This bar should be of round steel shafting and sufficiently longer than twice the length of the cylinder so that while doing the work the cylinder will not strike the dead or live centers of the lathe.

It should be at least two and one-half or three inches in diameter so as to remain rigid. This bar is fitted with the cutting tool a little farther than the length of the cylinder from the dead center end by boring a hole through it and filing it out so that it will admit the cutting tool. The tool should be at least one inch wide and preferably five-eighths or three-quarters of an inch in thickness. This tool may be held in place by fixing a setscrew at right angles to the tool through the bar.

In the boring operation the lathe should run at slow speed and the cylinder on the slide rest fed to the cutting tool in the usual manner. But under no circumstances should the lathe be stopped until the tool has cut the full length of the cylinder. If it is, you are sure to have a little bump, or a depression. In reboring a cylinder it is always best to take two light cuts—one through and the other back with the same tool, the rear end of the cutting edge of which is slightly relieved so that when coming back for the second cut it will leave a smooth surface.

[This is a second answer to the problem published in the SCIENTIFIC AMERICAN of May 9th. The other answer was published in the issue of June 24th.—ED.]

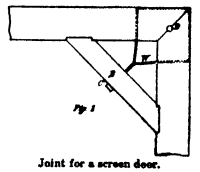
A Simple Vise

By B. Francis Dashiell

THE accompanying engraving shows a very handy and easily made vise or clamp. *At A* is a piece of dressed hardwood 12 inches by 2 inches by 1 inch. It is screwed upon the bench or table top. Another piece *B* of the same dimensions is screwed on about

Vise for a bench top.

8 inches away and at an angle of 30 degrees to *A*. A triangular piece *C* with its hypotenuse about 15 inches long is used as a wedge.

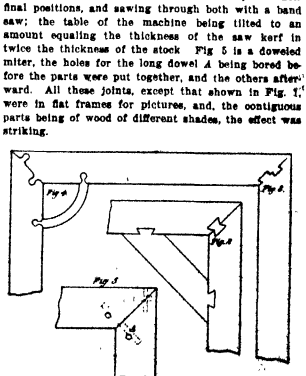


The stock that is to be worked is placed up against the piece *A*, and the wedge *C* is driven up tightly, thus clamping the stock firmly.

Some Oddities in Joints

By W. D. Graves

VISITING a friend, the writer's attention was engaged by a number of jointures which, while they would hardly appeal to the operator of a fully equipped wood-working plant, are all thoroughly practical—however odd—and might well be used by any one lacking the equipment necessary for the expeditious making of more conventional ones.



That shown in Fig. 1 was in a screen door corner, and was very secure. The stock was mitered, a wire *W* carried around the corner, through holes as shown by the dotted lines, and the ends passed through a hole in the brace *B*, through a washer *C*, and secured

Joint for a screen door.

in a common nut by pouring the hole full of solder. Turning the nut twisted the wire and drew the joint tight. The pin, or dowel, *D* served to keep the parts from sliding out of place while the wire was being tightened.

Figs. 2 and 3 are self-explanatory, being merely adaptations of the miter and dovetail combined. Fig. 4 is a joint on essentially the same principle but was made by tacking adjoining pieces together, one on top of the other, but otherwise relatively in their final positions, and sawing through both with a band saw; the table of the machine being tilted to an amount equaling the thickness of the saw kerf in twice the thickness of the stock. Fig. 5 is a doweled miter, the holes for the long dowel *A* being bored before the parts were put together, and the others afterward. All these joints, except that shown in Fig. 1, were in flat frames for pictures, and, the contiguous parts being of wood of different shades, the effect was striking.

Joints for picture frames.

The Inventor's Department

Simple Patent Law; Patent Office News; Inventions New and Interesting

Principal Examiner John I. Brown

PRINCIPAL Examiner John Ingalls Brown is the "spring-wheel" man of the Patent Office, the division 41 is in his charge, including spring wheels in the class of resilient tires and wheels which, with railway draft appliances, make up the division 41, in Mr Brown's charge since it was organized

Principal Examiner John I. Brown.

some years ago. While Mr. Brown is essentially a Maine man, he was born in Philadelphia, returning with his parents from that city to their former home in Maine when a child and continuing to reside in Bangor, where he attended the public schools

After teaching school and studying law, in 1884 he was appointed an assistant examiner in the Patent Office He has served in two examining divisions and for some years in the classification division prior to his appointment as principal examiner and the institution of division 41 of which he has had charge for some years

Raised as he was on the Maine coast, Mr Brown has never lost his love of sailing Sailing, however, is not Mr Brown's only hobby, for he is very much of a "joiner" being a member of the Sons of the American Revolution of the Knights of Pythias and of the Odd Fellows To the latter he has devoted much attention, is a member of every branch of Odd Fellowship and one of the most distinguished members of that order, being known wherever the order has found its way throughout the United States He is a grand representative to the Sovereign Grand Lodge I O O F. District of Columbia, and was the Grand Master in 1898

Mr Brown is a member of the bar of the Supreme Court of the District of Columbia, and is now and has been for many years, president of the Beneficial Association of the Interior Department, which Association comprehends the various bureaus of the said department.

The class of resilient tires and wheels is a very active one at the present time because of the great interest in spring wheels and the like as substitutes for cushion tires in automobiles, while resilient tires including cushion tires and pneumatic tires will likely be active as long as automobiles and similar vehicles are used.

A Mechanical Willow Stripper

THE mechanical basket willow stripper with an automatic adjustment to compensate for the variation in thickness of rods has at last been made. The basket willow industry is practically the last of the agricultural crops in which labor-saving machines have been introduced For over a hundred years willow growers have been looking for a machine that would successfully remove the bark of commercial willow rods used for making baskets and other articles Five years ago Mr. George S Herrick, a machinist of Syracuse, New York, undertook the task of designing a machine that would do the work Mr Herrick had already invented several other labor-saving devices, and after learning what an enormous amount of work was required to take rod after rod and remove the bark by hand, which is at best a very tiring and monotonous task, it occurred to him to make a mechanical willow stripper It was a year before he had a machine to try out, and in 1907 he made his first experiment with one which he patented and which proved very encouraging to him and the willow growers around Syracuse At the end of every season Mr Herrick had another machine to try out and each time with a little more practical experience he finally succeeded in making one that does the work On May 31st of last year he patented his mechanical stripper, which is in every way a labor-saving device, and will not only save farmers tens of thousands of dollars every year but will greatly stimulate the industry both in this country and abroad The primary object of this mechanical willow stripper is to supersede hand labor, and with the advent of this machine comes an increased and multiplied opportunity for making basket willow growing very profitable, which under our extensive methods of management, is almost impossible without a machine that will remove the bark at a comparatively small cost The average laborer by the old method of peeling can remove the bark from 75 to 125 pounds of willow rods in a day If the rods are all of an average size Assuming a laborer's wages to be $1.50 per day, the cost of peeling will be about 1½ cents per pound The willow stripper, on the other hand, will peel as much in an hour as one man can peel in a day

When willows are peeled after the sap is up in the spring there are only from thirty to forty days in which to do the work In order to peel all the rods from ten acres the grower is obliged to hire a small army of men, women, and children The required labor is often very difficult to find The mechanical stripper will do the work of ten men and will save the farmer's money and temper, for it will strip his willows more cheaply than if done by hand It is estimated that hand peeling costs about $35 per acre The machine can do this work in just one-tenth of the time and will cost between $3 and $4 per acre It is safe to estimate that the farmer will save approximately $30 on each acre Mr Herrick stripped steamed willow rods right along through January, February, and March, and averaged 125 pounds of rods an hour, which is all that one man can handle in operating the machine Mr Herrick is now designing an automatic feeder, by means of which the daily output will be greatly increased Of course the amount that can be stripped in a day will vary greatly under different conditions and with rods of different sizes and varieties The superiority of this machine over the ordinary brake can hardly be overestimated The brake (Fig 1) is a simple device consisting of a round steel rod from ½ to ⅝ of an inch in diameter and about 4 feet long which is doubled over so that the two ends are brought together, making a double rod 2 feet long The lower or welded end of the parallel rods must be inserted in a log placed at a convenient height The brake must be perpendicular and have the upper ends of the prongs slightly curved out one inch from the top so that the rods can easily be put in the brake. The operator places the thick end of the rod between the prongs of the brake and draws it toward him and the bark is at once separated from the wood The small end is then treated in a similar way, which completes the peeling Figure 2 shows the method of operating the brake

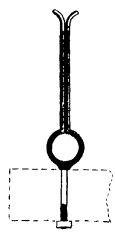


Fig. 1.—The old type of hand-brake.

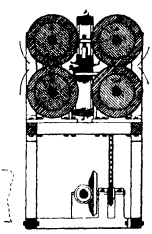

Fig. 5.—Cross-section of the new willow stripper along line x-x of Fig. 4.

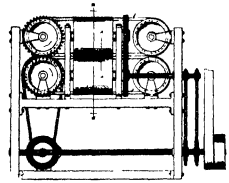

Fig. 4.—Longitudinal section of the new willow stripper.

The mechanical willow stripper is

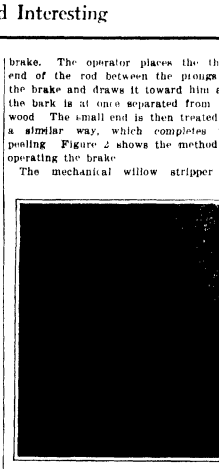

Fig. 3. The mechanical willow stripper.

illustrated in Fig 3 The operator inserts the butt ends of from 2 to 6 rods at a time between two rapidly revolving rubber-faced rollers which are slightly furrowed and which form a suitable feeding device. These rollers which are in pinching contact, are disposed to receive the willow rods transversely and to crack and split the bark throughout their entire length

After the butt ends of the rods have passed through the first pair of rollers (Fig 5, *r*) they pass between two parallel horizontal rubber belts (Fig 5, *bb* at *a*) disposed to receive the willow rods transversely between them These belts, which are known as stripping-members, move in a direction at right angles to the rods passing between the first pair of rollers and are designed to strip the bark from the rods These belts are driven at a comparatively slow speed, while the receiving or feeding rollers are operated at a relatively high speed The faces of these two horizontal belts are in close contact and have their contacting faces correspondingly beveled so that the rods may readily pass between them (Fig 5, *a*) The rods are pushed between these two horizontal belts by the feeding rollers and are then received on the opposite side by the second set of rubber-faced rollers of similar size and are operated at a speed equal to that of the first set of rollers The second pair of rollers are designed for drawing the stripped rods from the belts as is seen in Fig 3

Every part of the machinery is carefully adjusted, but like all other machinery the willow stripper is not perfect It will doubtless be continually improved Having undergone, however, nearly five years of trial and improvement before it was offered to the public it is much further advanced than a good many other labor-saving machines when they are first placed on the market The machine itself, though simple in the extreme, is about as inspiring to the willow grower as the reaper was to the wheat grower It removes the bark from small and large rods by the same turn of the wheels and does not seem to discriminate between the branched and unbranched ones (Fig 6)

The full extent of what the willow peeler will achieve for the grower still

Fig. 2.—The old method—stripping with the hand-brake.

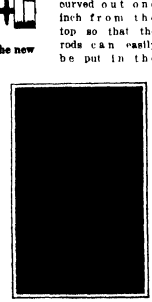

Fig. 6.—Rods stripped by the machine.

remain to be seen, but it will at least make him independent of an army of shiftless and itinerant laborers required every spring for peeling willows. It will make willow growing a scientific industry like that of the other minor farm crops. It means a new era in the basket willow industry.

How I Invented the Air Brake—IV*

By George Westinghouse

BEING fully impressed with the idea that if the wave of air which was utilized for signaling could be made to operate the triple valves upon the cars, there would then be an almost instantaneous application of the brakes upon the front, rear and other portions of the train, this idea, with hard work and a large number of experiments, shortly produced what is now known as the quick action automatic brake. The Westinghouse train was left at Burlington in order that the new triple valves with the quick action attachment could be applied and further experiments made. The valves as developed for this emergency proved to be successful, and the tests made with this train after their application were eminently satisfactory to the railway officials. It was thereupon arranged to take this train to Minneapolis and St. Paul, Milwaukee, Chicago, St. Louis, Cincinnati, New York, Albany, through to Boston and New England, to Washington, and then to Pittsburg, numerous demonstrations being made during this journey of some thousands of miles. This train, drawn by two locomotives, was frequently run at speeds above 50 miles an hour, and the tests were witnessed by all of the prominent railroad people of the country. So great was the demand for good brakes on freight trains that considerable difficulty was at first experienced in promptly filling the orders of railway companies. Nevertheless, the wide publicity given to these tests, coupled with a public demand for the adoption of means to prevent accidents, brought about the enactment of a law by the Congress obliging the railways to apply brakes and also automatic couplers to all freight trains in the United States within a time named in the act, which time was subsequently extended because it was physically impossible for the railway companies to make the introduction within the time first prescribed. The quick action automatic brake was operated like the first automatic brake for ordinary train movements; the quick action resulted only when it was necessary to apply the brakes for an emergency.

No sooner had the quick action automatic brake been developed to operate successfully on trains of fifty cars than new conditions were presented. Steel freight cars carrying enormous loads had in the meantime been developed and freight locomotives had been increased in capacity, so that trains were often composed of seventy to eighty cars, and more recently some trains have had as high as one hundred cars. This possibility had, however, been foreseen, and experiments were constantly being carried on to so improve the apparatus that it could be used to control trains of any practical length, and these experiments also had in view the more nearly instantaneous action of the brakes for ordinary service purposes than was possible with the automatic brake or with the quick action brake. The result was a most important development.

The present improved triple valve has the emergency feature, but it also has what is known as the quick-service application feature, that is, for ordinary purposes, the air is admitted to all of the brake cylinders so quickly that the longest freight train can be handled with almost the precision obtainable in the control of passenger trains of from six to twelve cars.

In the matter of the development of the brakes for operation upon passenger trains, nothing that skill and perseverance could suggest has been omitted in securing the highest degree of perfection. The requirements during the past few years, by reason of the greater weight of cars and locomotives and of the higher speeds at which they are run, have necessitated the redesigning of all the passenger train brake apparatus, including the method of attaching the brake shoes to the cars and the levers and connections for bringing these shoes to bear with the required pressure upon the wheels. For the purpose of insuring the highest efficiency, every wheel of a passenger train, including those under the locomotive, is now acted upon, whereas formerly many of the master mechanics and engineers were apprehensive that it would not be possible to make use of all of the wheels of a locomotive for braking purposes.

During the past twelve months, most elaborate tests of the latest form of apparatus for passenger service have been carried out under the direction of officials of several railways and of the Westinghouse Air Brake Company, in order to prove the operativeness of the new constructions and their capability to insure the highest degree of efficiency.

From the very beginning of its operations, the brake company has maintained a strong staff of experienced engineers, some of whom are located in each of the large railway centers and whose services are always at the command of the railways. It is the duty of one or more of these trained men to proceed to the scene of any accident that may have occurred in order to ascertain the cause, to report thereon, and to render such aid and co-operation to the railway officials as will tend to avoid a like accident if in any manner the brake can contribute to that end.

The air brake company has always had in its works, for experimental purposes, sets of brake cylinders, pipes and couplings, representing the apparatus upon trains of various lengths, so that tests and demonstrations could be readily made for all sorts of purposes, including educating or informing railway officials who came to seek information. To more effectively spread this information, the company, about fifteen years ago, constructed and equipped a special instruction car in which were arranged fifty sets of brake cylinders and pipes equivalent to like apparatus upon a freight train. This car was provided with a boiler to drive the air-pump for the production of the air under pressure needed to operate the brakes. Operative models of all parts of the apparatus were shown in section, so that their construction and operation could be more quickly comprehended. This car, in charge of experienced instructors, was moved from place to place, and engineers, firemen, conductors and other train employees in general visited it to familiarize themselves not only with the operation of the brake, but with its construction, and in this manner there has been developed throughout the country a knowledge of the air brake art which has proved of inestimable value to the railway corporations and their patrons. The records of the Westinghouse Air Brake Company show that to December 1st, 1910, their instruction car traveled over 113,000 miles. Numerous railways have also provided their own instruction cars, so that it may be safely said that every railway employee having anything to do with the operation of trains, freight or passenger, has been required to familiarize himself with the working of the brakes and to so study the subject that he could pass an examination, 280,258 employees having so far been examined by representatives of the Westinghouse Air Brake Company, and in numerous cases these men have been required to show sufficient knowledge of the brake to entitle them to receive certificates of their proficiency.

The importance of the maintenance of the brake to railways has not been overlooked by railway officials. They have appointed superintendents of brakes and numerous inspectors, and to-day there is an association of air brake officials organized in 1893, and now having 1,015 members, who meet annually in convention to thoroughly discuss the questions which are constantly arising, so that at present there exists an organization of which scarcely any of the public has ever heard—an organization which is constantly devoting skill and energy to the care of apparatus which above everything else in connection with railways contributes to the safe transportation of passengers and freight.

I have often been asked how many lives have been saved by the use of the air brake, and I have as often said it might well be a great many thousand, but that it was impossible to make even an approximate estimate. At a banquet given in Washington to the members of the International Railway Congress, in May, 1905, a diplomat, in speaking on the subject of the importance of railway brakes, said he felt safe in saying the air brake had saved more lives than any general had ever lost in a great battle.

I have spoken of four chief developments. It has been necessary, in order to avoid disastrous consequences, that each development should be of such a kind that cars fitted with newer apparatus could operate with little inconvenience with cars fitted with earlier apparatus. As it stands to-day, scarcely any of the old type of brake and the first type of automatic air brake are in use, but should a car fitted with the first form of automatic brake be found and put into a train with the more modern apparatus, such older apparatus would be found to operate fairly well with the more perfect form. The prevailing idea in the development and introduction of the brake has therefore been an adherence to such uniformity of apparatus that the interchange of traffic over various roads could go on uninterruptedly.

There is probably no apparatus now in use which has received such thoughtful consideration and been the object of such care in every one of its details as what is now popularly known as the air brake, and which is in universal use in the United States and in many other countries of the world.

In my estimation, there could be no better illustration of the value of the maintenance of standards than has been given by the manufacture and introduction of air brakes upon railways, for without such standards, train brakes would not have come into general use, with consequences which railway officials and the public can well appreciate.

My story would be incomplete without a reference to the powerful assistance which the railways of this and many other countries have rendered. They have been lavish in providing those facilities for making the thousands of tests which were necessary to progress in the developments I have recited; to the Pennsylvania Railroad especially, upon which the most important experiments were first made, the other railways of the country, as well as the traveling public, owe a debt of gratitude. When a railway (as did the Southern Pacific two years ago) provides a new train of one hundred steel cars to be fitted with the newer form of automatic brake, in order to carry on, with a staff of skilled men under the direction of the chief officers of the company, a series of experiments upon its heaviest gradients, requiring several weeks, for the purpose of securing greater safety and an increased carrying capacity per train, with the consequent lessening of the cost of transportation, it is just that the managers of such a corporation should receive credit for their far-sighted policy. To name the railways and to merely state chronologically the tests of brakes which have been made during forty years would require several volumes.

* From Presidential Address presented at the Annual meeting of the American Society of Mechanical Engineers.

Notes for Inventors

A Narcotic Cartridge.—Karl Durgemüller of Kretensen, Germany, has been granted a patent, No. 993,028, for a means for temporarily narcotizing animals, in which a cartridge filled with a mixture composed of substances containing cap-sicine in an immediately gasifiable form and of easily inflammable substances to accelerate the gasification, is combined with a small quantity of an explosive agent between the mixture and an explosive cap with which the cartridge is provided.

A Curious Anticipation.—An old practitioner before the Patent Office tells of filing an application for patent for a Texas inventor for an improvement in the cutlery class. The invention was unique and examination of the previous patents in the same class failed to develop anything to limit the novelty of the invention in any degree. Much to the attorney's surprise, in acting on the application for patent, the Patent Office Examiner cited, in anticipation of the device, the identical article which the assistant examiner having charge of the application had purchased in Nova Scotia while on vacation many years before, had brought to the United States and had been using on his desk in the Patent Office for more than the statutory period.

Beauty and Invention.—With a woman's appreciation of the importance of anything that aids beauty, Anna Taylor, of Ottawa, Ontario, Canada, has patented, No. 994,619, an artificial eye lash. It is made with a crescent shaped strip of material supplied with adhesive so it can be held in place and short lengths of hair held on the underside of the strip and projecting outwardly from its convex side.

Handling Ships' Cargoes.—The more convenient handling of ship cargoes, is the purpose of the invention of Onofre Lindsay of Valparaiso, Chile, and his patent, No. 994,171, includes a cable way which is fixed at one end and is movably supported at its other end to which is releasably connected a counterpoise. The haul rope, which is endless, engages the counterpoise and also extends around the fixed end of the cable way.

A Swimming Device.—Just in time for the bathing season is a patent to John A. Edwards of Birmingham, Ala. His invention is a swimming device and provides a number of floats to rest on the surface of the water. These floats support an elevated frame work, and hangers drop down from the frame and are connected to the swimmers in the water.

A Pot That Serves Tea or Coffee.—It may be desired to serve several beverages such as tea, coffee and cocoa and Jos. N. Papendry of East Liverpool, Ohio, has patented No. 994,949, a combination pot, which has a number of independent compartments to receive the different beverages. A single spout has openings communicating with their respective compartments and valves control these openings are worked from a point near the handle so the person pouring can open any particular valve and so cause tea, coffee or cocoa to discharge from the spout.

Automobile Accidents and Their Prevention.—Many automobile accidents appear to occur most frequently from breaking or derangement of the steering gear or the bursting or throwing of a tire. It was suggested that in many plants, and machines, duplicate parts were provided which could be quickly brought into use in lieu of broken or otherwise disabled ones, and that possibly this could be done in the case of an automobile parts retained to insure

with the duplicate parts so arranged as to be brought into play, automatically or by the driver, when the original part was disabled. My friend said he thought it would be a good thing, but he did not see how it could be done. Neither did I, or I would do it and reap the reward of a very valuable invention.

An Ingenious Sign.—Much ingenuity and sometimes considerable invention is involved in the production of signs and display cards used by merchants in their show windows. We recently noticed in the window of a paint store a sign made up of a plate of sheet metal on which water was represented. Four slits were made, one near each corner of the plate, and through the upper slits projected the feet and legs of a large doll, while the arms projected outwardly from the rear through the lower slits and appeared to be reaching out for small cans of paint. These cans of paint were placed on sand which had been strewn upon the floor of the window to represent a beach, the whole presenting quite a realistic appearance On the sheet were written the words "Come in," the effect being that of a diver whose arms and legs projected above the surface of the water, but whose body was submerged The sign attracted much attention, and an amusing feature was to notice children, who almost invariably would look behind the sheet to see the rest of the figure. The idea of this sign is obviously capable of many modifications.

German and American Saws.—German carpenters use, instead of hand-saws of the form familiar to every American, those of the buckssw type, only with a narrow blade, which as a rule must be slightly turned out of the plane of the frame, in order to take in boards of a greater width than would be possible otherwise, owing to the middle bar. The result of this position of the blade is a tendency on the part of the frame to turn downward out of the slightly inclined plane in which it lies, so that there is always a strain on the workman's wrist, and often the work is not straight. There is in this style of saw the further disadvantage, that in sawing diagonally across the middle of a piece of work consisting of two boards at right angles to one another, no inclination of blade to frame will enable the piece to be worked I have often asserted this, and recently in my own house was compelled to lend a carpenter who was shortening a bench my American saw—of what the Germans call the "fox tail" pattern. I think that if American saw makers would combine and send a man over there to manipulate the American pattern on work where it can be used and the German buckssw type can not, there would be an opening for good trade.

Why Not a Brazing Machine?—He was a working man with whom the writer got into conversation at the sea shore. The man said he was a coppersmith, and that he had worked in all the navy yards from Maine to California. His talk about his work was full of interest, particularly about the assisting machines and apparatus employed in the various manipulations of copper. It was astonishing to learn that no machine had been produced for use in brazing copper, but that the operation was still carried out entirely by hand No reason is seen why the inventive faculties could not be advantageously employed in solving this problem.

An Ozone Apparatus.—An ozone producing apparatus was patented May 23rd, 1911, to Octave Patin of Paris, France It is made with two concentric glass tubes separated by an annular space, an inner electrode frictionally engaging within the central tube and outer electrode of wire forming a helix and wound in spiral form upon the outer tube and projecting a metallic envelope for the outer tube.

Legal Notes

The Flare-back in Court.—An important patent case, that of John J. Knapp, Trustee, vs. the United States, awaits decision in the Court of Claims, having been argued before that court some weeks ago. The suit is under the general jurisdiction of the Court and not its special jurisdiction of patent matters. The invention forming the subject of the suit seeks to prevent flare-backs in heavy ordnance, and seems to be of much importance to the ordnance branches of the Government, and hundreds of pages of expert testimony, provided on both sides, and extensive illuminating briefs of counsel indicate the importance of the case, which is said in some quarters to involve claims for damages of upward of a million dollars

Iterations in Patents.—The importance of avoiding any alteration in an application for a patent after it is signed and sworn to is emphasized in a decision of Assistant Commissioner Tennant in the case of Ames *vs* Lindstrom, decided October 8th, 1910, in which the Assistant Commissioner, after referring to the alterations made in the application subsequent to its execution and prior to its filing in the Patent Office, says: "The application of Lindstrom is therefore not an application upon which a patent can be granted and cannot be given the effect of a constructive reduction to practice" He further says "As Lindstrom cannot be given the benefit of the filing of his application as constructive reduction to practice, Ames is entitled to an award of priority"

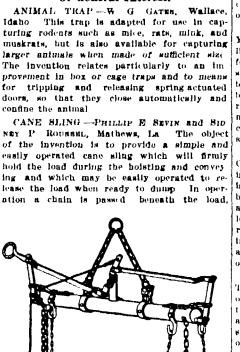
Plaster Works and Their Use.—In holding an optical prism device "of scientific or technical character," pressed to shape in plastic glass, for modifying light rays, not of the class intended to be covered by section 5, sub-paragraph I, of the Copyright Act of March 4th, 1909, Justice Stafford of the Supreme Court of the District of Columbia, in Brock vs National Electrical Supply Company, said "The objects are formed of glass when in a plastic condition by the use of a mold, and so, perhaps, may be considered in a liberal sense 'plastic works,' although, of course, fragile and brittle in their completed state. It is insisted that they are 'of a scientific or technical character,' because they are scientifically or technically produced It is not claimed that they are intended for, or adapted to, special use, in any science or in any branch of technic . . It seems clear to the court that it was the use to be made of the drawings and the plastic works rather than the knowledge or skill required for their production that was referred to in the words, 'scientific or technical' Hence it is believed that the objects exhibited are not of the class intended to be covered by the clause in question, and consequently that the plaintiff's bill is insufficient."

Pure Food and Trademarks.—The Patent Office will not pass favorably on an application for registration of a trademark for a meat product until at least one of the labels filed is stamped by the Bureau of Animal Industries of the Agricultural Department, "Approved, B. A I" The purpose of this is to prevent the registration of any mark for meat products until the products have been approved.

Recent Adjudicated Patents.—Out of seven adjudicated patents reported in the *Patent Office Gazette* of June 6th, 1911, only two were held void in whole or in part. In one of these cases, Anton vs Grier Bros Co (C C. A.) 185 Fed Rep., 796, one claim of the patent was held void as an aggregation of old elements In the other case, that of Heatonville M & F. Pass. Ry. Co. vs. McDuffee (C. C A.), 185 Fed Rep., 798, the patent was held to be void as having been granted on an amended application and claim which was a distinct departure from the original.

RECENTLY PATENTED INVENTIONS.

These columns are open to all patentees The notices are inserted by special arrangement with the inventors Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN

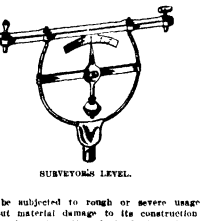


Of Interest to Farmers.

GRAIN WEIGHING SCALE.—A. McLEOD and A T McLEOD, Bloomington, Ill Material is received into a stationary hopper and discharges therefrom into a vertically movable weighing-hopper, so suspended and connected with pivoted weighted beams and other mechanism, that, when a certain load has been received, the weighing-hopper descends a little, whereby a valve controlling discharge from the receiving hopper into the weighing-hopper is closed, and then the gate at the bottom of the weighing-hopper is opened to allow the discharge of the grain or other material therefrom

Of General Interest.

ANIMAL TRAP.—W G GATES, Wallace, Idaho This trap is adapted for use in capturing rodents such as mice, rats, mink, and muskrats, but is also available for capturing *larger animals when made of sufficient size* The invention relates particularly to an improvement in box or cage traps and to means for tripping and releasing spring actuated doors, so that they close automatically and confine the animal



CANE SLING.—PHILLIP E SEVIN and SID NEY P ROUSSEL, Mathews, La The object of the invention is to provide a simple and easily operated cane sling which will firmly hold the load during the hoisting and conveying and which may be easily operated to release the load when ready to dump. In operation a chain is passed beneath the load,

CANE SLING

through the stirrups of a chain which passes above the load and into engagement with the pin When the cord is pulled and the chain slide released the lower chain pulls through the stirrup, releasing the load The embodiment shown in the illustration herewith is especially adapted for heavy loads, since the chains separate beneath the load The complete combination consists of a socket, a pin and a locking pin for preventing detachment of the socket and pin

SURVEYOR'S LEVEL.—WILLIAM M JACOBS, Vale, Ore The level pictured in the engraving presents a side elevation of the complete instrument, which is for use specifically as a simple surveying instrument for determining inclinations, grades, levels, etc It

SURVEYOR'S LEVEL.

may be subjected to rough or severe usage without material damage to its construction It may be easily adjusted should its calibration be disturbed The invention provides adjustments and mechanisms for varying the sensitiveness of the grade indicating mechanism

MEANS FOR RAISING SUNKEN VESSELS.—JAMES SKATSCHKOFF, 1 Degtiarnoiperoulok, St Petersburg, Russia. In carrying out this invention, a case or casing is made of waterproof tarpaulin which is open at the bottom, the case resembling the form of the vessel which is to be raised The case thus consists of a top portion and side walls, which latter extend down far enough to inclose the upper portion of the hull of the vessel

CAGE TRAP.—I RAMIREZ, Matamoras, Mexico This invention relates to cage traps, and while the trap is designed more particularly for rats and mice, the features of construction may be utilized in traps intended more specially for catching other animals alive The chief object is to produce a trap that will be efficient in operation and entirely safe for human manipulation, even by children

CARGO HANDLING APPARATUS.—O LINDSAY, Valparaiso, Chile, S A This device transfers cargoes at sea from one vessel to another by means of a cableway, stretched from the first to the second and upon which suitable carriages having conveying receptacles thereon are arranged to travel, the cableway being connected with means for keeping the same taut, to permit the carriages being easily hauled thereover by hauling means engaging the carriages and extending from one vessel to the other

SUBMARINE BOAT.—G B YERTON, New York, N Y Embodied in this invention is a life-boat for attachment to a submarine craft, for rescuing the crew of the craft should the same sink or become dangerously disabled when beneath the surface of the water The life-boat is for removable attachment to a submarine craft, the boat being secured in such a manner that the boat may be released by the crew or one of the crew, in a very short space of time

SAVINGS BANK.—C A WALKER, Stratford, Conn The invention provides improvements in banks or boxes, whereby the closure cap is conveniently placed in position on the box body and held therein against removal by unauthorized persons, without the use of special locking devices, and whereby the cap can be readily removed for the use of a special implement in the hands of a proper person, to allow of emptying the bank of its coin or other contents

BLIND IRON.—F S HARDEN, Salida, Colo The invention is an improvement in blind irons or stiffeners such as are ordinarily used in the blinds of harness, and has for its object a stiffener which prevents the breaking of the stitches or leather of the blind by rubbing, or other causes, at point of attachment of the winker brace, and the brace from being torn out

Hardware and Tools.

PLIERS.—P G STOMMEN Johnstown, Pa An object of this invention is to provide a pair of pliers which will enable the operator to bend wire or like members into either a curved or straight form, and further permit of the operator exerting a firm but quick increasable hold on fragile, delicate or diminutive articles

SAFETY WINDOW LOCK.—E V AMATO, New York, N Y. The invention provides a plate located upon one sash and carrying pawls, each forming a practically closed loop, provides a locking member having the form of a casing and adapted to be located upon the other sash, and also having means for engaging any one of the pawls, and provides means for holding the pawls in positive engagement with the casing

COMBINED PROTRACTOR AND T SQUARE.—F A DEL CASTILLO, Washington, D C The object here is to provide a combined protractor and T square, for the use of draftsmen, engineers and others and arranged to permit of setting the blades of the square to any desired angle indicated on the protractor or to accurately fasten the blade in right angle position relative to the base of the protractor

Heating and Lighting.

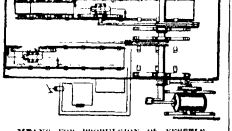
HEATING APPARATUS.—M MÉRAN and M M MÉRAN, 155 Rue du Faubourg Poisonnière, Paris, France This air and gas mixer provides before combustion as perfect and intimate as possible the quantities being supposed suitable, so as to obtain a flame furnishing maximum heat, which latter is increased or reduced by variation of the gas burner Means provide raising to the highest possible temperature a refractory body which will subsequently radiate its heat without detriment to gas combustion The refractory body is of such shape that it can undergo said dem *expansion* without cracking or splitting

Household Utilities.

ELECTRIC IRONING DEVICE.—G A RICKS, La Fayette, Ind This device is adapted to overcome the difficulties common with movable tools, and the object of the inventor is to provide a suitable support for a flexible conductor, and a means for protecting the conductor to keep it off the working surface and away from the tool and to prevent an interference with the working of the tool

AUTOMATIC WEATHER STRIP.—G L GODFREY, Steuben, Maine. This strip is for use on closures such as doors and the like, to prevent moisture or inclement weather from getting into a room through the space ordinarily found between a closure and the casing thereof For this, use is made of a casing provided with means engaging a second casing in con-

motion with a packing, and spring controlled means for automatically raising or lowering the packing when the door is opened or closed

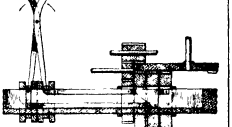


Machines and Mechanical Devices.

METAL STAMPING PRESS.—E H VOGEL, New York, N Y Mr Vogel's invention refers to presses of the kind used for stamping and performing analogous operations, such as punching, shearing, bending and the like, his more particular purpose being to provide a mechanism for increasing the efficiency of the machine, while promoting simplicity of operation and cheapness of operation

SLOYD MAKING MACHINE.—R A GOODE, Andover, Maine Generally speaking, this improvement comprises a feed wheel provided with pockets for picking up skewers one at a time from a hopper, and a dressing which parallels with the feed wheel, but slightly eccentric in relation thereto the purpose of the wheel being to grind off adjacent ends of the skewer blanks while the latter are carried partially around by the feed wheel

COIN CONTROLLED APPARATUS FOR VENDING MACHINES.—O J HOTALING, Johnstown, N Y The device is one which can be used with other vending machines, which serves to prevent the operation of the machine with which it is employed unless the suitable predetermined coins are introduced into the coin slot, which can be adjusted to operate with one or more coins of different kinds, which requires little power to actuate it, which does not modify or affect the operation of the machine, and which is so made that unauthorized or improper operation thereof is accomplished only with difficulty



MEANS FOR THE PROPULSION OF VESSELS.—WILLIAM H WHITE, Homewood, Charles St Ave Baltimore, Md The invention illustrated by the engraving relates to means for propelling marine vessels One object is to provide an improved form of slidable plate for carrying the driving pistons An other is to do away with friction caused by the use of inclosing pipes or chutes for the pistons There are several advantages her-

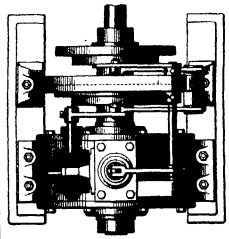
MEANS FOR PROPULSION OF VESSELS

over that form of the device shown in Mr White's prior patent There is no surrounding tube or pipe below the bottom of the vessel in which the pistons move The sliding plate is raised from near the bottom of the vessel The compressed air chamber is disposed so as to cover both slides and a portion of the operating mechanism therefor Air pressure is maintained in the chamber by air pumps Friction is reduced and the slide plates do not fit airtight

POWER TRANSMISSION DEVICE.—ANDREW J SIEBEN, Schawka Neb In this illustrated invention the object is to provide a device in which a direct forward or a reverse movement may be attained by the use of a clutch member carried by the main shaft It provides a device in which forward

POWER TRANSMISSION DEVICE.

and reverse movement may be attained by simple mechanism, thereby eliminating the annoyances occasioned by a multiplicity of parts and reducing cost of manufacture to a minimum It may be used on automobiles or other devices in which a forward and reverse movements are used, and means are provided whereby variable speed movements may be attained



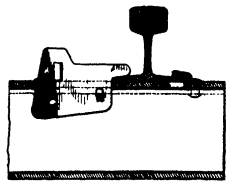
BRICK MACHINE.—A S BACON, Oklahoma Okla The object of the invention is to provide an improved brick machine especially adapted for use in the making of cement brick, which will receive the plastic material and pressed into shape and having means for expeditiously removing the pressed brick onto a pallet for removal from the machine

COMBINED PUMP AND AERATOR.—R W KELLY, deceased, SARAH KELLY, administratrix Atchison Kan *In the present patent* the object of the inventor is the provision of a new and improved combined water pump and aerator, for use on cisterns, wells and various other water supplies and arranged to aerate the water wherever the pump is actuated for lifting or raising water.

PRINTING MACHINE.—W JACKSON, New York, N Y The invention has reference to wall paper printing machines, and its purpose is the provision of certain new and useful improvements in printing machines for printing wall paper borders, whereby the paper after it receives the imprint by the printing rolls is accurately cut lengthwise along the contour of the imprint

Prime Movers and Their Accessories.

ROTARY ENGINE.—WILLIAM J MCMANAMY and JOHN P JOHNSON, care of Thompson and Stout, Whipps Block, Kalispell, Mont A plan view with parts in section is given herewith in the illustration of this invention



ROTARY ENGINE.

which relates to rotary engines, particularly for steam or other gaseous driving agents, and which has for its object to provide an engine capable of working efficiently in any position, with especial provision of means to prevent or reduce the leakage of steam Two or more cylinders and pistons may be used, combined so that their working periods will alternate or overlap, so as to avoid dead centers The construction of the piston of two separate parts, allows for expansion and contraction The packing rings may be held against the piston by steam

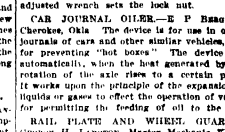
Railways and Their Accessories.

RAIL FASTENING FOR METALLIC RAILWAY TIES.—ALEXANDER BRYDON'S Main St West Easton, Pa Mr Brydon's invention illustrated herewith is an improvement in rail fastenings on which a rail-clamping plate is arranged in a slot in the top of a metal tie arranged adjacent to the rail base supported on the tie The fastening is preferably

RAIL FASTENING FOR METALLIC RAILWAY TIES.

formed as a cotter-pin whose upper edge is inclined to form the wedge proper It may be readily detached by withdrawing a wedge when the plate will drop down into the tie, thus leaving the rail proper free of obstruction on the inner side, so that it may be readily detached from the lugs and removed from the tie

NUT LOCK.—THOMAS F MAY, Lehi, Utah Mr May's invention is an improvement in nuts locked by means of a smaller jam nut The

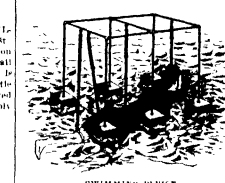


NUT LOCK.

engraving represents a vertical cross section of a railroad rail provided with fish plates secured by a bolt provided with his nut-lock Both nuts being of the same size and form, one wrench of fixed adjustement serves to screw them both home, or to remove both from the nut. Not only does one wrench serve to put on and take off the nut, but it holds the bores of the main and lock nut in alinement, while both are being put on and removed from the bolt, thus preventing the locked nut from turning so as to bring its axial bore out of alinement with that of the bolt nut. The same adjusted wrench sets the lock nut.

CAR JOURNAL OILER.—E P BRADMAN, Cherokee, Okla The device is for use in oiling journals of cars and other similar vehicles, and for preventing "hot boxes" The device oils automatically, when the heat generated by the rotation of the axle rises to a certain point. It works upon the principle of the expansion of liquids or gases to effect the operation of valves for permitting the feeding of oil to the box

RAIL PLATE AND WHEEL GUARD.—GEORGE H LANGTON, Master Mechanic K. C., So Ry., Shreveport La The invention relates to rails for railways and the aim is to provide a guard, for switch points, to guide the wheels of a train safely over the switch point and prevent a derailment For this purpose use is made of a base plate for attach-



RAIL PLATE AND WHEEL GUARD.

ment to a railway tie and adapted to receive a rail thereon a rail plate on the base plate and extending upwardly and inwardly to engage the rail and wheel guard formed on the base plate and extending toward the rail plate, the guard wheel being spaced from the said rail The plan view shows herewith a switch with the device applied thereto at the switch point end of the switch

Pertaining to Recreation.

SWIMMING DEVICE.—JOHN A EDWARDS, 3701 Avenue F, Birmingham, Ala The device pictured herewith shows the manner in which a swimmer is supported It comprises a plurality of floats a frame-work arranged

SWIMMING DEVICE

upon the floats and supported by them, and adjustable means attached to the frame-work for supporting a swimmer in the water It is inexpensive to manufacture and in supporting a person it is so constructed as to allow the free use of the swimmer's limbs at all times

Pertaining to Vehicles.

RESILIENT WHEEL.—W F MASTERS, New York, N Y The invention has in view a wheel having a tire with roller bearings arranged between the wheel body and the tire, which tend to expand the tire and to keep the latter under tension by a flattening strain, or a tendency of the tire and body of the wheel to rotate relatively Other wheels, such as pulleys, can be constructed in accordance with the invention

WIND SHIELD.—I H SPRAGUE, Norwalk, Ohio In this shield the movement of the upper section is controlled and limited by two distinct separate and connecting means One of these permits the two sections to move as though hinged together or permits them to be held with their adjacent edges spaced apart and in different planes The other serves to lock the two sections in their adjusted position

Designs.

DESIGN FOR A PAPER CUTTER.—D F CALDWELL, New York, N Y This ornamental design for a paper cutter shows an implement of substantial and graceful form, the blade and handle end having the same width through the entire length The scroll work and other ornamentation represent design of excellent artistic quality

MORE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

NEW BOOKS, ETC.

THE BLUE GOOSE CHASE. A Camera-Hunting Adventure in Louisiana. By Herbert K. Job, State Ornithologist of Connecticut. New York: The Baker & Taylor Company, 1911. 8vo.; 331 pp.; illustrated. Price, $1.25 net, postage 12 cents.

It is not a bad idea to get boys interested in the newer kind of hunting—that is, a hunting with the camera rather than with the gun Taking as his theme the rediscovery of the winter haunt of "the blue goose, the author takes his boy heroes on queer jaunts, across the Louisiana marshes, and through water and fire, imparting by the way an accurate knowledge of Nature and her children of fur and feathers.

ELECTRICIANS' OPERATING AND TESTING MANUAL. By H C. HORSTMANN and V H TOUSLEY. Chicago: Frederick J Drake & Co., 1910. 359 pp.; 16mo.

The first few chapters of this little book give an introductory review of the fundamental definitions and points of general theory Then follows a description of the several types of dynamos and motors, hints for the operation of these machines, chapters on transformers, batteries, lamps, testing, locating dynamo and motor troubles, etc. The print is excellent. The book is bound in a soft leather cover, which adapts it for pocket use.

MOTOR BOATS SIMPLY EXPLAINED. By John Douglas. London: Percival Marshall & Co. 16mo; 98 pp., illustrated.

The first chapter is devoted to hull construction—the "carvel" system, the smooth-skin hull, the clinker build—with drawings and specifications for a simple launch, some brief discussion of the different styles of boats, and a description of the hydroplane The second chapter describes the motor and has some very clear diagrams showing the various types and their operation Fuel, ignition, and driving-gear furnish the subject for other chapters, and hints on the maintenance and running of a pleasure launch follow. The price of this English publication, the Thames rules and regulations are given in an appendix

PLUMBING AND HOUSEHOLD SANITATION. By J Pickering Putnam Garden City, New York Doubleday, Page & Co., 1911 8vo; 718 pp., Illustrated Price, $3.75 net

"Plumbing and Household Sanitation" is on a higher plane than most works of a similar nature Mr Putnam's standing as a member of the leading architectural guilds perhaps accounts for this From cover design to final illustration it is an attractive book to scan, and a close study of the text confirms our first impression of careful preparation and full treatment. The aim is the discovery of the best and simplest methods of insuring a healthy home Types of appliances and methods of construction are presented, and the reader is educated up to the point where he may safely use his own judgment as to the best appliances, of which there are such a multiplicity that merely to catalogue them would exhaust the space at command Many ideas and conclusions are advanced which the writer admits to be not quite orthodox But he believes that it is now possible for one to demonstrate for himself at slight expense whether the contentions put forth in such cases are correct He has done much in the past to introduce advanced methods and to depress the cost of appliances "Simplification" is his slogan Among other things he advocates the omission of the main house trap, and puts forward practical means for otherwise simplifying the systems generally in use

PENROSE'S PICTORIAL ANNUAL. Edited by William Gamble 1910-1911 Vol. 16. London: Percy Lund, Humphries & Co., Ltd 8vo, 192 pp

There is a period in the development of the child when he becomes ashamed to be seen with a "picture book" Later he finds that the love of pictures is not a thing to conceal, but a thing to enjoy openly with the rest of the world, young and old. Certainly no one need be ashamed to be seen with the Pictorial Annual, even though his only object be childish, unalloyed pleasure in the beautiful reproductions it places before his eyes But the work has a further purpose than merely to give pleasure and excite admiration It represents the year's progress in process work Its splendid illustrations are given as examples of the perfection to which the art has been brought. These examples comprise, besides hundreds of smaller engravings, more than one hundred and seventy full page plates in from one to ten colors. Such reproductions as that of Constable's "The Valley Farm" are strikingly beautiful and effective. The text is a worthy accompaniment to the gallery of art, and deals with the difficulties and achievements of a fascinating craft in a thoroughly practical manner "The Decadence of Aquatint and Stipple in England" is the subject of an article by Charles Harrop. Edmund G. Gress gives us "An American View of Typography." And there are articles on two-tone processes, filigree three-color reproductions, photographically-designed advertisements and illustrations, and on other subjects embracing a great variety of means and methods.

LEGAL NOTICES

PATENTS

INVENTORS are invited to communicate with Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D. C., in regard to securing valid patent protection for their inventions. Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured.

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our Hand-Book on Patents will be sent free on request.

Cases in the Oldest agency for securing patents: it was established over sixty five years ago.

Inquiry No. 9439.—Wanted, addresses of parties who can furnish [illegible] for [illegible]

Inquiry No. 9440.—Wanted, addresses of firms manufacturing [illegible]

George Ellery Hale

(Continued from page 28.)

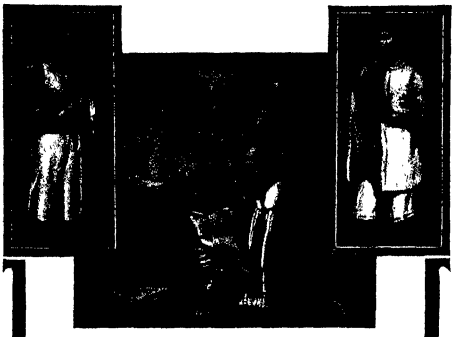
displacements of the lines of various elements; discovery of magnetism in the sun by the photography of vortices and the detection of the Zeeman effect in the spectrum of regions around sun spots; investigation of the flash spectrum of the chromosphere, hitherto observed only for a second or two during a total eclipse of the sun; study of the general circulation of the solar calcium vapor and the local movements near sun spots, and a general investigation of sun-spot spectra, including wave lengths and origin of sun-spot lines, cause of weakened and strengthened lines, etc. These items will be sufficient to indicate the general nature of the work that is being done under Prof Hale's direction at the present time.

In addition to his observatory achievements, Prof Hale has rendered valuable service to science in two other ways, first, by the founding of the *Astrophysical Journal*, the leading publication in its field, secondly, by organizing the International Union for Co-operation in Solar Research This union held its first meeting in St Louis at the time of the World's Fair in 1904 Subsequent meetings have been held in Oxford, England, in 1905, Meudon, France, in 1907, and on Mount Wilson, California, in 1910 At the last meeting there were 84 delegates representing 12 different countries—a splendid tribute to Prof Hale, the founder and always the prime mover in the union

The value of Prof. Hale's work reckoned in dollars and cents would not be rated very high in Wall Street But considered from a higher standpoint, as a contribution to human knowledge it must be accorded a most prominent place in the science of the day The sun is a star It is by far the nearest star to the earth, and can be most easily studied Any addition to human knowledge in regard to the sun is a contribution toward the interpretation of the stars in general and of the universe as a whole.

This point of view has been brought out in Prof Hale's book, "The Study of Stellar Evolution" Prof Hale has been a very prolific writer, but this is the only popular work that he has published in book form For over twenty years he has been a contributor to the leading technical journals of astro-physics and astronomy

Sailing the Seas in a "Cockleshell"



(Continued from page 36)

was for a run of 2,200 miles to the Azores, 900 miles from the Azores to Gibraltar, and another 900 miles to Rome via the Straits of Bonafacio

Not many days after the "Seabird" had set sail to the eastward there came into New York Harbor another little yawl, the "Pandora," which has just accomplished, on a much larger scale, the ocean-sailing feat now being attempted by the "Seabird" The "Pandora" is much bigger than the "Seabird," having, indeed, a length on deck of thirty seven feet, nine inches, and measuring some nine tons

The "Pandora" was built in Australia for two experienced navigators, Captain George Blythe, of Coventry, England, and Captain Peter Arakakis, a Greek She was constructed for the express purpose of making a voyage entirely around the world, sailing to the eastward The trip was made partly for experiment, but more in search of adventure On May 3rd of last year, she set sail from the port of Bunbury, West Australia, and she has just completed her trip across the South Pacific and around Cape Horn to this port. She is not unlike the North Sea fishing boats; and her beam of fourteen feet gives her at once good stability and abundance of accommodations for her owner and skipper.

The craft set sail from Bunbury on May 3rd of last year and coasted to Melbourne, which was reached on May 29th. On July 10th, following, the coasting trip was continued, the next port of call being Sydney, which was reached August 16th; and the following day the little craft was headed eastward for New Zealand this being, of course, the real start of the deep-sea voyage. The run to Auckland is described by the Captain

as being the worst of the entire voyage. On August 28th the wind rose to the strength of a gale and then to a hurricane. The boat was stripped to bare poles, and even at that, shipped a heavy green sea, which swept her full length, and flooded her cabin. Part of the bulwarks was carried away. Finding that the craft could not run safely before a big following sea, she was hove to with a sea anchor. The sea anchor parted and a further section of the bulwarks was torn away, but with the aid of a trysail on the main mast the "Pandora" rode out the gale and reached Auckland, New Zealand, September 4th. There she remained for repairs until October 2nd, when she left for the Pitcairn Islands, which lie 2,750 miles east of New Zealand. On November 21st she passed the Pitcairn Islands and reached Easter Island on December 12th. After a brief stay the "Pandora" started for the Falkland Islands and made her stormy run around Cape Horn, which she passed on January 16th.

On January 22nd, during a fierce hurricane, the vessel was driving under bare poles and lashed wheel, when a heavy sea fell upon the vessel, turned her bottom up and finally, as the masts went by the board, brought her around again to an even keel, the little craft having been turned through a complete circle from left to right. A Norwegian whaler opportunely hove in sight and towed the "Pandora" two miles to the New Islands, where she was laid up for repairs.

She left the Falkland Islands on March 4th, for St. Helena, and sailed thence on April 26th, reaching Ascension Island on May 3rd. On May 7th, she started for New York, which port she reached June 23rd.

After spending six weeks in New York the two captains start for London on their journey via the Mediterranean and the Suez Canal.

Psychological Apparatus for Testing Chauffeurs

(continued from page 89)

the smoked paper. The tuning fork vibrates one hundred times a second, so that each of these indentations marks one-hundredth of a second on the smoked paper. The slightest movement of the wheel, clutch, throttle, or brake in response to the signal flashed by the electric bulb, completes an electric circuit and drops the corresponding pointer on the revolving drum where it begins tracing a line on the smoked paper. And the number of vibrations of the tuning fork before wheel, clutch, throttle, or brake is in operation shows the hundredths of a second that have elapsed between the sight of the signal and the response of the mechanism—in other words the reaction of that pasticular chauffeur under that particular emergency.

With the three colors and the three apertures in the screen in front of the motorist, candidates for the privilege of driving motor cars in public places could be tested for the promptness and efficiency with which they would do the right thing under practically every possible emergency. Mr. Ricker has suggested the following table of signals:

White light in left opening—turn to right.

White light in right opening—turn to left.

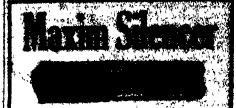
White light in centre opening—slow down.

Three white lights—turn or slow down quickly according to position.

The white lights, it will be seen, represent conditions of ordinary travel. The green lights—which bring into play both foot clutch and steering wheel—are more serious, ranging from a released clutch and a turn to right or left according to the position of a single green light to a released clutch and a sudden swerve when three lights become visible. The red lights, finally, call for the emergency break as well as the released clutch and a quick manipulation of the steering apparatus—and three red lights at once might be fairly translated into "imminent death" and make a corresponding demand upon the reactions of the automobilist.

Suppose, for example, that the candidate has mounted into the dummy motor, has had the meaning of the various lights explained to him, and has been allowed to practice with them until the unfamiliarity of his position has worn off and his attitude is normal. Then the real test begins. A white light suddenly appears in the centre of the screen. It means "slow down" and the candidate reaches for the lever and makes the necessary movement, the time being caught and recorded on the smoked paper of the revolving cylinder. Then come three white lights in the centre, which again mean "slow down" but mean also, "be quick about it or somebody may get hurt!" The candidate again handles his lever, but this time the record on the smoked paper should show that he did it very much quicker than in the first instance. And so through various other combinations—with somewhere among them the sudden flashing of the three red signals and the record showing how many fractions of a second were needed for each saving movement at a moment when a difference of a few fractions of a second might in a real automobile be all the difference between a living motorist and a dead one.

Naturally the man whose nervous system is not actually up to the demands that may at any moment be made upon it in motoring would find it difficult to get permission to run a motor, but the average citizen would hardly feel that the weeding out of motorists fundamentally incapable of meeting the more serious emergencies would be a public misfortune.



[The reading of this article suggests the following comment. The chauffeurs reaction to a given signal comprises two separate and distinct steps, namely, first, interpreting the signal, and, secondly, responding to the particular emergency which such interpretation implies. What is measured is the sum of these two steps. This sum does not necessarily stand in any simple relation to the time required for the second step alone, and it is this and this only which is of interest in actual practice, where the danger signal is not some peculiar combination of lights, but a perfectly plain and unmistakable situation of real life. Probably the reading of a complicated set of signals would take longer than the response to it, even if the person under examination had been allowed previous practise. These considerations raise some doubt as to the value of the test proposed.—Ed.]

Railway Building in Asiatic Russia: Paris-Peking in Nine and a Half Days.

At the present time Russia has railway communication with her Pacific seaboard only through Manchuria. If you consult maps of Asiatic Russia published during the past eight or nine years you will find the route of a proposed railway indicated along the Amur River from Khabarovsk to Stryetensk on the Shilka (an upper tributary of the Amur); i. e. entirely within Russian territory. According to the *Revue Générale des Sciences* a credit has been voted for the completion of this railway. Another great project about to be undertaken will give St. Petersburg direct railway communication with the Trans-Siberian *via* Viatka, Perm, and Ekaterinburg, to Kurgan, in place of the present route *via* Moscow. Most important of all, it is proposed to build a railway from the termination of the present Chinese line, which extends from Peking to Kalgan, across the Gobi Desert, along the route of the old Chinese post road, *via* Sair-usu and Urga, to Kiakta, south of Lake Baikal. This would enable travelers to journey from Paris to Peking in nine and a half days!

Water Tunnel Beneath Manhattan Island.—The water supply tunnel which is to run at a depth of several hundred feet below Manhattan Island for distributing the water which will be brought down from the Catskills by the aqueduct, will be built for $19,864,627, which, in view of the fact that the estimated cost was $25,000,000, must be considered very satisfactory.

Aeronautics

Progress of the Paris-London-Paris Aeroplane Circuit Race.—After several days of bad weather, which delayed the start of the fourth stage of the race from Utrecht (Holland) to Brussels (Belgium), twelve of the fourteen aviators that arrived in Utrecht started for Brussels on June 26th. The distance of this stage was 93¾ miles, and the total distance to Brussels 455¾ miles. Even after waiting two days the aviators were obliged to fly in a violent wind and heavy rain showers. Lieut Conneau was the first to reach Brussels. He alighted in his Blériot at 5:30 P. M., and was followed soon after by Vedrines on his Morane monoplane. The latter was presented with a laurel wreath with the inscription, "To the Victor of the Paris-Madrid Race." In all seven aviators arrived up to 9 P. M., Renaux, with his passenger, being the last, with a total time in flight for the 455¾ miles of 39 hours and 49 minutes. Lieut Conneau's time was 37 hours, 27 minutes, and the times of the other aviators were as follows: Kimmerling, 37 34; Vedrines, 38 01; Garros, 38 23; Gibert, 38 56; Duval, 39 07, and Wynmalen and Vidart, who arrived the next morning, 52 46-32 and 60 52 52.

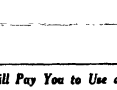
Delivering Mail by Aeroplane.—Upon the departure of the huge "Olympic" on her first eastern trip from New York on June 28th, Aviator Tom Sopwith attempted to drop a message on board the steamer when she was passing through the Narrows. Accompanied by Richard R. Sinclair, he left the aviation field at the Nassau Boulevard at 3 27 P. M. He flew over Brooklyn and circled above New York Bay. At length, when 1,000 feet in the air, he discovered the "Olympic" just as she reached the Narrows. He made for the liner post haste, and flew down to within 200 feet of her before dropping the package. This missed the deck by a few feet and was lost in the bay. Nevertheless the possibilities of the aeroplane for delivering mail were demonstrated in a practical way. As the speed of an aeroplane can be regulated so that it is no faster than the speed of a giant liner, it is possible for the aeroplane to come up astern of the liner and hover above her while mail and packages are not only dropped aboard the steamer, but while they are also hoisted up to the aeroplane to be brought ashore.

Accidents in the Fourth Stage and Results of the Fifth Stage of the European Circuit Race.—On account of the extremely bad weather conditions, several aviators came to grief in the fourth stage of the above-mentioned race. M. Tabuteau fell and wrecked his Bristol biplane at Glize, a short distance from the Belgian frontier. Vidart (Deperdussin monoplanes) and Prevost and Train were also stalled at the same place. Train completed the race the next day, as did also Wynmalen whose H. Farman biplane was stalled 35 miles from Brussels. Le Lasseur's Blériot fell near Breda, slightly injuring the aviator. Barra arrived at Brussels the evening of the 27th. His M. Farman biplane landed heavily, but he was not injured. Emile Train arrived the same evening. He was the last one to finish this stage. The winner of the race to this point received a cash prize of $8,000, and also $3,000 additional for winning the fourth stage. The fifth stage of the race a distance of 56¼ miles from Brussels to Roubaix (France), was flown by ten of the competitors on Wednesday, the 28th ultimo. Vedrines was the first in this stage of the race. He arrived at 11 04 A. M., having covered the distance in 58 minutes 46 seconds (57.4 miles per hour). His fast flight won him the biggest part of the $3,000 prize given by the Roubaix Exposition for the fastest time. Garros arrived second at 11·17 A. M., his time for the 56¼ miles being 1¼ hours. He was followed by the remaining aviators in the order named: Kimmerling (time, 1:11). Conneau (1:24), Vidart (1:58), Renaux (1 54), Gibert (2·06), Valentine (1 37), Train (4:09), Prevost (4:43). Wynmalen and Barra postponed their flight until the next day on account of the heavy winds. Duval fell before he reached the frontier. His Caudron biplane was wrecked, but he was not seriously injured.

Electricity

Explosion in a Nitrogen Plant.—According to a press report the nitrogen works at Trostberg, Bavaria, were recently destroyed by an explosion. At this plant, in which American capital was invested, nitrogen was recovered from the atmosphere by the electric arc.

Wireless Telegraph Station.—The German Postal and Telegraph Department is taking measures to erect wireless telegraph stations on the Baltic at Swinemund and Konigsberg, and another will be installed on the North Sea on the Sylt Island. It will be remembered that wireless plants are already in operation at Heligoland, Cuxhaven and Norddeich. This latter station, which ranks among the principal wireless plants of the Continent, is soon to be enlarged.



Telephones in Fire Alarm Boxes.—Fire alarm boxes fitted with loud-speaking telephones are now installed in the suburban district of Kiel, Germany, and they are placed at various points along the streets. This appears to be the first time in which loud-speaking telephones have been applied to fire alarm use. The telephones are mounted in an iron box, and upon opening the cover an electric contact is made which rings up the nearest Fire Department station. Owing to the use of such telephones the voice is always heard clearly, in spite of the street noises.

Lighting the Turin Exposition.—For lighting the grounds at the Turin Exposition, there is to be used a very neat method. As the grounds extend along the sides of the river for some distance, it was decided to use 130 arc lamps, which will all be connected in series, so that the current coming from the city mains at 6,300 volts can be used directly for the whole system. For a given number of lamps it is a well-known fact that the size of the wiring is cut down as we raise the voltage. For instance, if all the present arc lamps had been connected in series of four upon a low voltage of 220 volts, 29 tons of copper would be needed for the wire. By using 130 lamps in series only two tons of copper are required. The new German Conta lamp is used.

New Lamp Filament.—A new metallic filament for incandescent lamps is made by the Regina firm, and it is having some success in Germany. Tungsten is combined with carbon by a process invented by Hopfelt. First a tungsten filament is made and this is covered with a layer of carbon by suitable means. This is said to give a very hard and elastic filament for lamps, and it runs on a small current. Some 32 candle-power lamps of this kind were put through a test at the Cologne municipal electric plant, and were found to burn for 2,000 hours and over in some cases. They take 1·04 watts per candle-power when new, and 1·13 after 2,000 hours' run. When the lamps are placed horizontally the life is less, or 1,500 hours. The new lamps are made in sizes up to 600 candle-power. Some of them have the new Euphos glass bulb, which is of a slight yellowish green hue, and absorbs the ultra violet rays, so that the light is safer for the eyes. The present lamps are made to run on 100 volts.

Re-chargeable Dry Batteries.—A new electric dry battery is now being introduced in London, according to the *Electrical Review and Western Electrician*, which is claimed to have a useful life up to three and one-half years, and as the deterioration when it is not in use is negligible it will retain its charge for several years. It may be re-charged several times in the same way as a storage battery. For the negative element a number of zinc plates are employed and for the positive element a carbon rod is imbedded in a composition formed of charcoal and manganese oxide, surrounded by a mixture of ammonium chloride, chloride of lime, and zinc chloride. These elements are placed in an electrolyte consisting of amylon, obtained from the sago palm, with exciting salts composed of platinum-ammonium chloride and zinc-ammonium chloride. This electrolyte, which is in the form of a jelly, is claimed to retain its moisture for long periods and to be but little affected by variations of temperature.

It Will Pay You to Use a Comptometer

Because—

It's a good adding machine—has twice the speed of any other

It is the easiest and fastest machine for all multiplications and divisions in business accounting.

It's dead-sure accuracy prevents mistakes

It is easily operated—you touch the keys, the machine does the rest

It has no lever to pull after each item; no carriage to handle, no ribbon to replace

It would seem impossible for us to do the work we are now doing without the Comptometer

Youngstown Comptometer Co.

Johnstown, N. Y.

Ask for our booklet "Rapid Mechanical Calculation" describing its uses in nearly every line of business, or, better still, write for a machine on free trial

You Can Now Purchase

A Complete Curtiss Power Plant With a Genuine Curtiss Motor and Propeller

Curtiss power plants have been used, tested and proven. When you buy one it relieves you of all worry on the part of the equipment. In other words it assures the success of your Aeroplane. No experimenting or thought on your part is necessary—it has all been done for you by skilled experts. You receive the finished perfected product.

Model "A" 4 cylinder, 25 H.P. Price $ 600

Propeller, radiator and equipment especially designed for each motor.

Curtiss Aeroplane Motor

THE CURTISS MOTOR CO. Hammondsport, N. Y.

SPARK COILS AND THEIR CONSTRUCTION

160 describes the making of a 1¼-inch spark coil and condenser.

1514 tells you how to make a coil for gas-engine ignition.

1522 explains fully the construction of a jump spark coil and condenser for gas-engine ignition.

1124 describes the construction of a 6-inch spark coil.

1067 gives a full account of the making of an alternating current coil giving a 5-inch spark.

1527 describes a 4-inch spark coil and condenser.

1402 gives data for the construction of coils of a definite length of spark.

This set of seven papers will be supplied for 70c. Any single copy will be mailed for 10c.

What we ask you to do

Simply send us the names and addresses of the people whom you think the Scientific American will interest and we will do the rest.

In response to the foregoing suggestion we have received from our subscribers the names of thousands of interested people.

What we do

We keep an accurate record of all names received in this manner and for each new subscription we get from any list we will extend the subscription of the person who sent us the list for four months. Thus if we receive three new subscriptions from any one list the subscription of the person who sent us the list will be extended for a full year.

Of course you may send as many names as you wish, the greater the number of names you send the larger the number of subscriptions we will probably receive and the longer the period for which your own subscription will be renewed.

Be careful to write the names and addresses plainly and don't fail to put your own name and the address at which you are receiving the Scientific American on each list you send.

Address all lists to the Circulation Department, Scientific American, 361 Broadway, New York.

ARTICLES *on* AVIATION
IMPORTANT AND INSTRUCTIVE

In the Scientific American Supplement we have published in the past few years papers by some of the most eminent physicists and engineers on flying machines. No book thus far published is so complete and so authoritative as these articles. The range of the articles is wide, covering as it does the theoretical side of aviation as well as those more practical aspects which deal with the construction of machines. The following is a partial list of the more important articles which have appeared in the Scientific American Supplement—see special note below.

Nos. 1816, 1817, 1818, 1819, 1820, 1821 and 1822. **The Practice and Theory of Aviation.** By Grover Cleveland Loening, A. M. This is the most complete paper on aeroplanes that has probably ever been published. Fourteen biplanes and monoplanes are described in detail, and illustrated with scale drawings, namely, the Farman, Cody, Curtiss, Wright, Voisin (old model), Voisin (new model), and Sommer biplanes, and the Antoinette, Santos-Dumont, Blériot XI, Blériot XII, Grade, Paberie and Pfitzner monoplanes. The proper dimensioning of aeroplane surfaces, as deduced by famous experimenters from their tests, is also considered. Taken as a whole this series of seven papers constitutes an admirable text book.

No. 1713. **The Wright Aeroplane.** This is a thorough description of the old type of Wright biplane with the horizontal elevation rudder in the front of the machine. Excellent diagrams and photographic views accompany the paper.

No. 1756. **Louis Blériot and His Aeroplanes.** Few people realize that Blériot's successful monoplane is the result of ten years of daring and perilous experiment. In this paper will be found an instructive description of the evolution of the present successful Blériot monoplane, illustrated with diagrams and photographs.

No. 1768. **The Farman Biplane.** A complete description of the Farman biplane, with detail drawings of the box tail and vertical rudders, the manner of working the four ailerons, hand and foot levers which control the machine, plan view and side elevation of the entire machine.

No. 1767. **The Santos-Dumont Monoplane.** An illustrated article describing the Demoiselle, the smallest and one of the fastest machines thus far made. Sketches accompany the article, showing the details of the construction and control.

No. 1582. **How to Make a Gliding Machine.** Full details and drawings which will enable anyone to make a glider for $15.00.

All these articles are profusely illustrated.

Special Note. **We will mail (gratis) a list of many additional important papers, in the Supplement, treating of aeronautics. Ask for list "A."**

Each number of the Supplement costs 10 cents, mailed, and you can order as many of them as you wish. A set of papers containing all the articles above-mentioned will be mailed for $1.20.

SCIENTIFIC AMERICAN
HANDBOOK OF TRAVEL

With Hints for the Ocean Voyage for European Tours and a Practical Guide to London and Paris

By ALBERT A. HOPKINS, *Editor of Scientific American Reference Book*

At last the ideal guide, the result of twenty years of study and travel, is completed. It is endorsed by every steamship and railroad company in Europe. To those who are not planning a trip it is equally informing. Send for illustrated circular containing one hundred questions out of 2,500 this book will answer. It is mailed free and will give some kind of an idea of the contents of this unique book, which should be in the hands of all readers of the Scientific American. It tells you exactly what you wish to know about a trip abroad and the ocean voyage.

WHAT THE BOOK CONTAINS

500 Illustrations	*The Sea and Its Navigation*
6 Color Plates	*Statistical Information*
9 Maps in pocket	*Automobiling in Europe*
All About Ships	*400 Tours, with prices*
"A Safer Sea"	*Practical Guide to London*
Ocean Records	*Practical Guide to Paris*

Names 2,000 Hotels, with prices

500 PAGES, 500 ILLUSTRATIONS
FLEXIBLE COVER, $2.00—FULL LEATHER, $2.50 POSTPAID

MONOPLANES and BIPLANES

THEIR DESIGN, CONSTRUCTION & OPERATION

The Application of Aerodynamic Theory, with a Complete Description and Comparison of the Notable Types

By GROVER CLEVELAND LOENING, B.Sc., A.M., C. E.

CRITICISMS

"The first treatise upon aviation which we have seen which may be styled really complete. . . . . Actual aeroplane designing is the central theme of the volume. . . . . The prominent types are exhaustively compared. . . . . The illustrations are a notable feature."
—*Rochester, N. Y., Chronicle.*

"A very complete account of the theory of heavier than air flying machines with a technical description of nearly all the present types of aeroplanes. . . . . Presents in compact shape the substance of aerodynamic theory. . . . . Easily comprehensible to the reader who can concentrate his attention. . . . . It is the most scientific popular book of the aeroplane that we have come across so far."
—*New York Sun.*

"Many writers have failed to realize the demand which exists for aero literature in which mathematical deductions are a necessary but not predominant part of a comprehensive exposition of the entire subject. For a writer to steer a straight course between the reefs of trigonometry on the one hand, and the superficialities of mere discussion in a popular vein on the other is to accomplish what can be done only by one who is himself a thorough student in the finer details, but who can sufficiently divorce himself from the mathematical atmosphere as to present the whole subject from a broad standpoint, making it readily intelligible and informative to the least erudite seeker after knowledge."
—*Phila. Inquirer.*

"Students learned in aerodynamics and laymen ordinarily interested in aviation will find equal delight in reading 'Monoplanes and Biplanes.' The book is a welcome addition to the libraries of those who have realized the future of aerial navigation, and denies a work treating solely of the heavier than air machines written by an acknowledged expert and with no hobbies hidden in the discussion."
—*Boston Journal.*

"While mathematics is his forte as becomes one who has written so superb a volume, Mr. Loening is also rightly generate as the most exacting scientist could demand. Here is a work which is at once a history and textbook which will be forgotten last, for everything that is within the range of actual knowledge. To say that 'Monoplanes and Biplanes' is at once now and authoritative with reference to the entire subject and that it is puzzled in the highest degree is the last praise due to this volume."
—*Buffalo News.*

"Mr. Loening has written, in fact, for the man who wishes to apply practically the experience that has already been gained."
—*New York Times.*

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are sharp, the articles short, and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately and in simple terms, the world's progress in scientific knowledge and industrial achievement. It seeks to present this information in a form so readable and readily understood, as to set forth and emphasize the inherent charm and fascination of science.

Montauk as an Atlantic Terminus

DURING the past few months, much has been published in the daily press about the proposal to build at Montauk, on the eastern end of Long Island, a large terminal harbor for the use of trans-Atlantic passenger steamers. The avowed object of doing this is to shorten the Atlantic passage and save two or three hours of time. The distance from Montauk to New York by rail is about 120 miles, and it is proposed that the steamships enter the new harbor and transfer their passengers to special railway trains, which in two or three hours time would land them at the new Pennsylvania station in the heart of Manhattan Island, thus saving a few hours over the steamship route.

It is probable that the recent propaganda is the joint work of the railroad company which controls the Long Island Railway system and certain of the steamship companies which are seeking permission of the government to lengthen the North River piers to accommodate the great length of their latest vessels. As far as the steamship companies are concerned, it is no doubt their belief that if the business interests of New York could be brought to believe that the construction of a Montauk terminus was being seriously undertaken, they would unite in an application for longer piers, so earnest and unanimous, that the desired government permission would be granted.

Now, although the SCIENTIFIC AMERICAN is an earnest advocate of pier extension, we do not believe that favorable action on the part of the federal government will be brought about, or even assisted, by such a palpable "bluff" as this talk about transferring the trans-Atlantic terminal from this city to a remote spot on the sparsely settled coast of the eastern end of Long Island. For the astute men of the engineer corps of the United States army are too well versed in those fundamental principles which govern the selection of terminal ports to be deceived by the arguments set forth. It is in accordance with those principles that New York is to day the leading port for trans-Atlantic passenger travel and, if reasonable enterprise is shown in providing adequate facilities, New York must ever remain the leading port.

Furthermore, if the geographical and other demands which have given New York its predominance were ignored, and a port were formed at Montauk, it is very doubtful if all the wealth and influence of the railroads and steamship companies combined could divert travel from the present to the proposed harbor.

No one doubts that it would be possible to build at Montauk a magnificent and ideal terminal for Atlantic steamships. It is easy of access; provides ample depth of water for the largest vessels, and in the matter of piers, purviews, railway facilities, and all the et cetera of a point of transfer from ocean to railway, it could be made the most perfect work of its kind. But when the harbor was completed, it is very doubtful if the traveling public would appreciate the supposed advantages thus provided.

The fastest of our modern liners, the "Mauretania," has crossed the Atlantic at an average speed of 26 knots, or over 30 miles an hour, and at this speed she would cover the 120 miles to New York in four hours' time. If, instead of proceeding to New York, she entered Montauk Harbor, and transferred her passengers to special trains, they would take at least two and a half hours to make the run to Manhattan. It is true that some hours would be consumed by the "Mauretania" at quarantine, and in steaming up the harbor to her pier in the North River; but there would be a similar delay at Montauk for quarantine and in warping the big ship to her berth for the discharge of the passengers. The ultimate gain in time would be possibly an hour and certainly not over two hours; and as an offset against this would be the inconvenience to the passengers of an extra transfer—that from the steamer to the train—an objection so serious that it would probably prove a source of very material loss in passengers to any steamship line that made use of Montauk as a terminal.

In the earlier days of ocean travel, when accommodations were cramped, and the ships were small and of slow speed, the shortening of the voyage by a few hours would have been a matter of some importance; but in these days of giant vessels, whose bulk is so great that they are steady in any but the heaviest seas, and whose accommodations are such that the traveler is surrounded with all the conveniences which he has come to look upon as essential to his daily comfort, the matter of two or three hours more or less on board ship is one to which he is supremely indifferent. Certainly he would not wish to exchange the spacious dining saloons, lounges and smoking rooms of an ocean liner for the relatively cramped and uncomfortable accommodations of a modern railroad train.

But there are even weightier considerations, largely of a geographical character, which show the futility of the attempt to artificially create a trans-Atlantic terminus, 120 miles distant from the commercial metropolis which it would be intended to serve. The selection of the site for the great ports of the world has not been determined either by caprice or accident. The existence of the magnificent New York Harbor at the point where that great natural line of travel from the west to the Atlantic seaboard by way of the Great Lakes, the Mohawk Valley, and the Hudson River, reaches the Atlantic coast, determined beyond any chance of later reversion where the principal meeting point of rail and ocean traffic would be found. The phenomenal growth of New York in population, trade and wealth was rendered inevitable by its splendid strategic position. The hundreds of miles of foreshore, the vast wharf and other terminal facilities (inadequate and capable of much improvement though they may be), the existence here of the terminals of the great railroad systems, the concentration here of the thousand and one trades and industries that cater to the ocean steamship, and finally the fact that within a few minutes of the landing wharfs are to be found the finest hotels in the country, and theatres and places of amusement by the score,—all these considerations, in addition to those of the inconvenience of transfer above mentioned, conspire to render the position of New York as the point of departure and arrival of Atlantic steamships forever permanent and unassailable.

Artificially Induced Mutations

IN the course of his work in elaboration of his theory of evolution through mutation, DeVries made the suggestion that alterations in the hereditary properties of organisms are due to changes in the germ plasm occurring before fertilization. In order to test the possibility of localizing such supposed changes, Dr. D. T. MacDougal (director of the Department of Botanical Research of the Carnegie Institution of Washington) started some far-reaching experiments about six years ago. Some of his general results have been referred to from time to time, but there has not until now been a complete account of what was done. This now appears in the *Botanical Gazette*.

A number of workers have attempted to obtain a modification of the developing embryo by placing the cut ends of flower stalks in various solutions, or by applying various solutions to the growing plant, but all results were negative. MacDougal adopted the plan of injecting the solutions into the ovaries of the plants just before fertilization was to take place. He used in his earlier experiments specimens of *Raimannia odorata* and *Oenothera biennis* which had been cultivated for several generations in pure cultures, where they showed no more differences than the ordinary fluctuating variations. The solutions used were various strengths of sugar, zinc sulphate and calcium nitrate in distilled water. The solutions were introduced into the ovaries by means of an ordinary hypodermic syringe. The first result of the operation was the casting off of the developing ovary in most cases. But some of the seed ripened in both species.

All the seedlings of the derived *Raimannia*, although ovaries from the three different treatments were represented, presented the same appearance—and that was different from the parental type. This evening primrose is a biennial: the derived individuals all ripened their seed during the first season. This involves not only the physiological character of whatever is concerned in early flowering, but the growth habit of the plant was entirely different from that of the parent. The *Raimannia* produces rosettes of leaves during the first year, the stem remaining very short; during the second season the stem elongates very rapidly, bearing leaves and flowers. Another difference between the original type and the induced derivative is perhaps even more striking. All the plants of this family regularly bear hairs on the skin of the leaves and stem. In the derived individuals the skin was quite free from hairs.

The results with the *Oenothera* were equally definite and were distinguishable from the very first. The cotyledons of the new plant are broader and of a brighter green than those of the original and the same is true of the leaves of the rosette. The plants have been cultivated for five generations and retain their new characters without any indication of a tendency to revert to the parent type. Specimens have been grown in different localities together with the parent form, and the differences remain constant.

The derivative of *Oenothera biennis* was hybridized with the parent form and resulted in a plant bearing intermediate characters, but being more vigorous in growth than either parent. The indications are that the derived *Oenothera* is a distinct type related to the parent but not intergrading with it.

Since 1906 over twenty species of plants chiefly desert forms, were experimented with. Although the fatalities among the experimental plants were high, owing to the action of ground squirrels, birds and other enemies, as well as to the results of the operations, a number of seeds were saved and grown. In a species of *Pentstemon* native to Arizona there appeared to be induced a new type as a result of the treatment of the ovarics, but whether the characters displayed by the derived individuals are really new to the species cannot be known with certainty since it has been impossible so far to obtain a pedigreed culture under control conditions.

The question of how the introduced solutions modify the reproductive cells cannot of course be answered by these experiments. In order to throw some light on this question, flowers of the giant cactus were used, with solutions containing methyl blue, and other flowers, with other pigments. On examining the flowers on the day after the injection of the dye, it was found that the solution had been absorbed in varying degrees by the different tissues of the ovary and ovules; but in no case had the pigment penetrated to the embryo-sacs. In the flower of the cactus the distribution of the methyl blue was such that the pollen tubes growing down into the ovary were affected. It would appear therefore that whatever effect may be produced by the solutions introduced into the ovaries is upon the pollen element rather than upon the embryo-sac nucleus. But the real nature of the changes produced is still unknown. It is impossible to observe the direct action of the reagents used upon the cell elements; this may be chemical, or it may be physical.

There are at present under observation seedlings from treated ovaries of about a dozen species of plants. While it is not yet possible to induce a desired mutation at will, these experiments will no doubt lead to results that will be of lasting practical as well as theoretical value.

Substitute for Platinum

IT has been suggested that, in the prevailing scarcity of platinum, the metal palladium might be a practicable substitute. It belongs to the platinum group, and has many of the qualities of platinum, although in some respects it resembles silver. Among its valuable characteristics are hardness, ductility and malleability. It is also decidedly non-corrodible. It occurs, along with nickel, copper, silver, gold, platinum, iridium and rhodium, in the ores of the Canadian nickel mines in Ontario. Out of 800,000 tons of these ores about 5,000 ounces of palladium are annually produced.

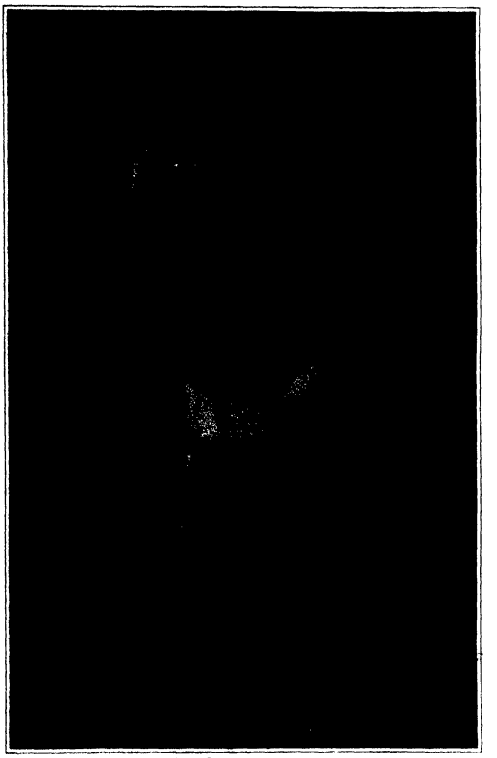
The Upbuilding of Our Merchant Marine

Our Extensive Foreign Trade and the Near Completion of the Panama Canal Call for Immediate Action

By the Hon. Charles Nagel, Secretary of the Department of Commerce and Labor

THE subject of the merchant marine has been discussed so exhaustively that the sole remaining question seems to be one of ways and means No one doubts that our merchant marine should in some manner be restored. Our coast line is so extensive, and the success of its marine service is so great, that the suggestion for an ocean marine is constantly kept before us. The marine service upon the lakes and along our coast emphasizes the absence of an ocean marine and strengthens the demand for legislative aid to foreign trade across the oceans.

This situation is accentuated by the fact that the Panama Canal is nearing completion. As it appears now, all the countries that control a merchant marine will be in a position at once to make use of this new maritime route. Our country, however, has taken no steps to the same end, but on the contrary our strength is dissipated in discussions about ways and means by which the merchant marine might be restored It looks to me that this delay may have serious consequences We not only lose the immediate opportunity and profit; but routes once established and connections made by foreign trade are not easily dislodged If our country wants to get the full benefit of this newly-created opportunity, with all it implies, we should be prepared at the inception to take full advantage of this route, established by our enterprise and with our money



The country which is first upon the ground with its goods has an undoubted advantage; and the country that sends its goods in its own bottoms at once gives the highest possible guaranty of its determination to maintain its trade In my judgment, one of the great advantages, if not the greatest, in having our own merchant marine, rests right at this point It is not only a question of profitable investment, and of the employment of money and men; but it is a question whether we shall give foreign countries with whom we propose to establish and maintain trade a guaranty of our good faith and continued purpose Neither government nor business is determined by material interests alone Impressions and sentiment are not to be disregarded. Foreign countries with whom we seek to establish intimate commercial relations will not be convinced of the earnestness of our purpose, until our country is prepared to have its consignments come into foreign harbors under our flag, to be delivered from our decks Such a pledge of our determination to sustain lasting relations would be accepted above all others.

Again, it is often said that foreign ships plying between our ports and foreign ports provide ample facilities for all our foreign commerce Superficially speaking, that may be true. There may be ships enough to accommodate all the trade between all the countries in question. But granting this to be true, in my judgment the real situation is not met These foreign ships sustain no commercial or administrative relation to our country. They do sustain, as a rule, the closest possible relation to the countries in which they are owned. I am not now speaking of the financial support, be it subsidy or something else, but I am speaking of the power which foreign countries exercise by way of making rates for purposes of successful competition on their part. It goes without saying that our commercial competitors everywhere sustain a much closer relation to their governments than probably would be possible under our political institutions. In foreign countries commerce has the immediate encouragement of government, participates in deliberations which go to the development of that commerce, and finds encouragement by way of protection of one kind or another The same thing is true of the carriers Rates are made to meet the demands of the situation, and it goes without saying that we do not enjoy exceptional rates when we undertake to compete with the commerce of those countries in which the ocean carriers are owned and controlled We have adopted a policy of equal rates for all shippers, and that rule is now pretty fairly enforced. We are therefore compelling our trade, under a regulation of this kind to compete with the commerce of foreign countries in which the same rule is not enforced It appears to me to stand to reason that we are therefore not in a position to compete upon equal terms We are compelled to depend upon carriers who are beyond our control, but who are free to respond to the demands of foreign trade when it is in competition with us

The situation is difficult enough with respect to our commercial organizations, upon whom we depend to introduce our trade into foreign countries We do not tolerate combinations in this country, whereas like organizations engaged in competition with us in foreign countries are systematically sustained. This, of course, is an unavoidable condition—a price we pay for the delayed reconstruction of our commercial forces. But it appears to me that such a condition should not be carried to an unnecessary length We depend upon a foreign merchant marine, which may, and no doubt does, give preference to our competitors We are confronted with the question of whether or not we can successfully complain even of a combination or a monopoly between all the foreign ocean carriers that enjoy the trade of our ports It appears to me, therefore, to be high time to consider ways and means by which we may restore our own merchant marine, to serve us impartially in competition, and to respond to such regulations as our country through our Government may see fit to impose upon such an agency

Of course I am aware that there are many other reasons that may be assigned for the restoration of a merchant marine It is apparent that a navy such as we have ought to be supplemented by a merchant marine, and that without such aid in case of need the navy is necessarily in a measure handicapped I prefer, however, to rest the case in favor of a merchant marine solely upon the commercial considerations which to my mind are conclusive

As to the means by which such a result is to be accomplished, I prefer to say nothing I think the issue has frequently been confused by the cry of subsidy, and by the contention that other countries do not subsidize, and that, therefore, we ought to be able to restore our marine without such assistance I think the facts show that in one way or another, most, if not all, countries which have a considerable merchant marine do give support Be that as it may, we are dealing with a condition and not with a theory We know that the enterprise of our country has challenged competition in nearly every field We know that we are making progress in the extension of our foreign trade We know that our lake and coastwise marine service is at least equal to that of any other country We must conclude that the absence of an ocean marine must have some reason other than accident or a lack of initiative If we are to compete successfully with foreign countries we must gage the instrumentalities which they employ And if we are unwilling to resort to their methods, then it must at least be for us to ascertain what we can and must do to engage in successful competition We cannot afford to rest upon our oars The day has passed when we can expect things to come to us because we have vast resources and great natural wealth The time has come when we must fight for our position in the field of commerce, and when we must take into account the means employed by others in determining what it is for us to do

Measurements of Subterranean Temperature

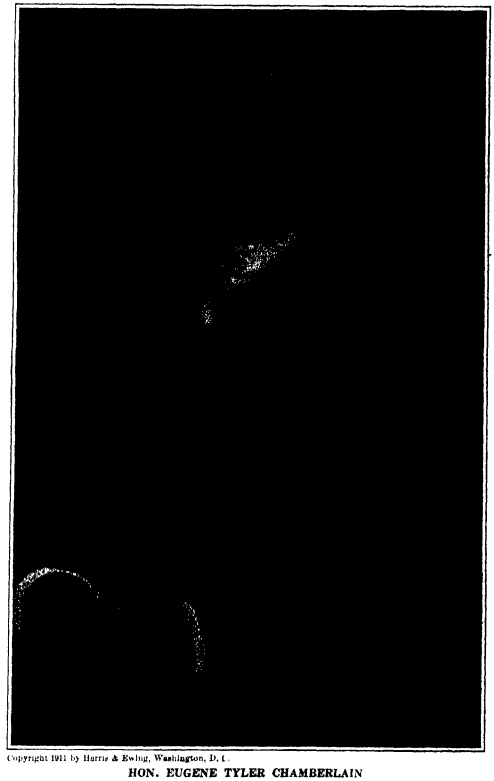
THE deepest hole in the world, up to date is the boring begun ten years ago at Czuchow Silesia with the object of attaining a depth of 2,500 meters and which has now reached a depth of 2,240 meters (7,349 feet) The bore is 44 centimeters in diameter at the top, and diminishes progressively to 5 centimeters Measurements of temperature have been made regularly At 2,220 meters the temperature is 83.4 deg. C (182 deg. F) This gives a "geothermic degree" (amount of descent corresponding to a rise of temperature of 1 deg C.) of 31.8 meters The change of temperature does not proceed uniformly In fact an interesting "temperature inversion" occurs between the depths of 640 and 730 meters, where the temperature actually falls, with descent, about 2 deg.

The American Merchant Marine

Analysis of the Causes Underlying the Amazing Growth and Rapid Decline of American Shipping

By the Hon. Eugene Tyler Chamberlain, Commissioner of the Bureau of Navigation

THE total tonnage of documented American shipping to-day in round numbers 7,500,000 gross tons—is second only to the British total of 19,000,000 gross tons On the Great Lakes alone we have 2,100 steamers of 2,500,000 tons, which in efficiency are unsurpassed, and in the aggregate are more than double the tonnage of Japan and greater than that of France Indeed, the fleet on our inland seas ranks next in tonnage to the 4,300,000 tons under the German flag, which visit every port in the world In view of these facts, the question may well be asked What signifies dissension in and out of Congress on the decadence of the American merchant marine? The answer is to be found in the fact that barely one-tenth of our tonnage is registered for the foreign trade, and that at the present time less than 500,000 tons are so engaged In oversea competitive navigation we barely hold the eighth place, and the absence of our flag in foreign ports is the subject of pertinent comment by travelers Our ships carry less than nine per cent of our exports and imports While the Congress has divided more or less on party lines over the choice between subsidies or free ships, practically every maritime nation except the United States has both systems and we have neither in effective form



Two generations of men now living saw the time when the United States was pressing Great Britain close for the commercial mastery of the seas The radical changes in our navigation have thus been effected within fifty years, but a cursory glance at simple gross tonnage figures may illustrate crudely the lines of our development in navigation Expressed in thousands of tons (ton equals 100 cubic feet), the following table shows for important periods the tonnage of our merchant shipping, together with its three lines of occupation—the foreign trade, the domestic coasting trade, and the fisheries

American Documented Tonnage.

	Foreign	Domestic	Fisheries	Total
1789	124	68	9	201
1800	667	272	33	972
1820	584	588	108	1,280
1860	2,179	2,645	329	5,353
1870	1,449	2,638	159	4,246
1910	782	6,669	57	7,508

Perhaps no other single thing better illustrates the courage and tenacity of purpose the political and business prescience and the broad humanity which inspired the fathers of the republic than their early and persistent attack upon the system of discriminations in navigation devised by Oliver Cromwell and relentlessly followed by the advisers of the House of Hanover against the Americans whom two wars had failed to subjugate "Those principles of liberal intercourse and of fair reciprocity which intertwine with the exchange of commerce the principles of justice and the feelings of mutual benevolence," as expressed by President J Q Adams in 1828, "were first proclaimed to the world in the first commercial treaty ever concluded by the United States in 1778 with France, and have been invariably the cherished policy of our Union" Our Presidents, from Washington to Taft, have consistently followed that policy, in which all parties have concurred Mr Adams added "whatever of regulation in our laws has ever been adopted unfavorable to the interest of any foreign nation has been essentially defensive and counteracting to similar regulations of theirs operating against us"

Up to 1820 the Federal statistical system was imperfect and inaccurate, so those figures in the table above must be taken with allowances. This period, too, embraces our own war of 1812 and the Napoleonic wars which disturbed commerce and embarrassed navigation During this period 180,000 men were required to man England's navy, while only 140,000 were employed on her merchant fleets England's absorption in war enabled the United States in the first part of the nineteenth century to begin to supplant her as the world's carrier

HON. EUGENE TYLER CHAMBERLAIN
Commissioner of the Bureau of Navigation.

The period of maritime reciprocity from 1820 to 1860 witnessed the greatest and most rounded development of American merchant shipping. In these forty years in both foreign and domestic trade our tonnage multiplied fourfold—a rate which has been surpassed for a corresponding interval only by the marvelous development of German shipping during our own day, inspired by Bismarck and sagaciously encouraged as a political as well as a commercial policy by the Imperial German Government At the present rate of growth modern Japan perhaps may make even more rapid progress. The growth of those forty years was due to natural causes The races of Northern Europe, with but a slight admixture of the Latin, combined to form the free population of the colonies which became the original States of the Union

Bred to the sea and confined to a narrow seaboard, these men and their descendants found occupation and profit as well as outlet for the spirit of adventure in navigation to all quarters of the globe. Ships were built of wood and our illimitable forests furnished abundant material, while England's depleted timber lands compelled her to import from a distance materials for naval and merchant fleets. The discovery of gold in California opened to our navigation a new trade which was restricted by law to American vessels But even during the period of its most rapid growth causes were at work to check American maritime progress and to promote the growth of British shipping. Of these the most influential was the increasing use of iron as the chief material of construction for ships' hulls. England's supply of iron was abundant, while our own supply was limited, and the advantage which the United States had enjoyed in its forests swung back to Britain and her mines of coal and iron The Fulton Centenary is fresh in the minds of all, and one need barely allude to the fact that from the outset Americans were among the first to apply steam to navigation. Yet the substitution of the steamer for the clipper ship, for reasons inherent to the nature of our people, was as effective in checking our growth as the substitution of iron for wood The nature of work and the kind of men to perform it on shipboard were revolutionized by this change The full-rigged ship demanded of its officers and crew intelligence, skill and daring in the open air, and of its owner enterprise and more or less of the speculative spirit In these Americans excelled The greater part of the work on the steamer consists in shoveling coal deep down in the hold, and for this kind of work the American has no adaptability. Even if the drain of the civil war on the young men of the North had not made it necessary for Congress to repeal the law of many years' standing requiring two-thirds of the crews of American ships to be Americans, it is certain that such a change before 1870 would have been forced upon the statute books. For the steamer, too, England had the coal which we at the time were producing in limited quantities She had the miners to serve as firemen and coal-passers on her steamers, while we were just beginning to dig on the surface of our mineral wealth

The causes named would have sufficed to have put England far to the fore even if the civil war had not turned Americans aside from commercial competition with foreign nations to armed conflict with one another. In the table above between 1860 and 1870 our fleets in foreign trade and the whale fisheries lost 1,000,000 tons—almost the exact measure of American shipping transferred to foreign flags through dread of the "Florida," "Alabama" and the "Shenandoah," or actually captured as prizes or burned at sea by the Confederate privateers

The policy of ocean mail subsidies adopted by England in 1840 and consistently followed since, has always stimulated the building of the highest types of steamships, and while the aim of the policy has been political the indirect benefits to British shipbuilding and navigation have been considerable. If Congress, at the close of the civil war, had passed a bill allowing our citizens to purchase steamers abroad and register them under the American flag for foreign trade, it is quite possible that the losses consequent upon the war would have been partly made up. To overwhelm the Confederacy required an immense number of sailors on our warships of all

descriptions, and these would have readily returned to merchant shipping. Five years, too, had not sufficed to turn our shipowners and shipbuilders from the sea to the land, nor had it destroyed their prestige in foreign ports. That course was not followed; on the contrary, an act was passed denying a return to the flag of any American vessel transferred to aliens "during the existence of the rebellion."

The first trans-continental railroad was completed in 1869 by the junction of the Union and Central Pacific railroads. From 1870 to the present time the railroad mileage of the United States has increased from 53,000 to nearly 350,000 miles. Without heaping up readily accessible figures these and the conclusions to be drawn from them suffice to show that after the war the capital and energies of the country were turned entirely toward internal development. Transportation by land, agriculture, manufactures, and mining absorbed all the capital and labor which formerly had been engaged in oversea shipping and many times more than those amounts. The bulk of our lake tonnage and much of our coastwise shipping is subsidiary to railroad and mining corporations. Even the Norwegian immigrants to the United States, sailors born, do not stop at our seaboard cities, but go west to the farms of Minnesota, the Dakotas, and already are moving thence into Manitoba and the remoter farm lands of Canada. The wealth and prosperity of the country as a whole and of individuals have undoubtedly been greater by this diversion than would have been possible by a persistent effort under adverse conditions to try to meet foreign competition on the ocean.

The table above shows that since 1870 we have virtually ceased to be a maritime commercial power competing with England, Germany, France and Japan, or even lesser commercial powers. Sixteen years ago we had a fleet of the four fastest and finest trans-Atlantic mail steamers, but these have long since been surpassed, and such trans-oceanic steamers as we have to-day owe their existence to the Ocean Mail Act of 1891, or to the anticipated passage of the subsidy bill of twelve years ago, identified with Senator Frye, former Senator Edmunds and the late Senator Hannar.

Vessels built in the United States and no others can engage in our domestic commerce. Foreign competition is cut off by prohibitory penalties. To this statute, dating from the early years of the republic, and to our naval shipbuilding programme, we owe the existence of such seaboard shipyards as we have to-day. On the lakes foreign competition is shut off by Niagara Falls and the limited capacity of the Welland Canal quite as effectually as by legislation Since 1870 our shipping on the Great Lakes has increased from 685,000 tons to 2,890,000 tons, while in forty years our shipping in domestic commerce along the seaboard has increased from 1,950,000 tons to 3,780,000 tons, or scarcely doubled.

The figures of our own maritime growth of course are inconclusive unless we compare them with the growth of other maritime nations during the last century and during the first decade of the twentieth century. A somewhat different method of statistical statement is necessary to present accurately the facts for so long a period. The merchant fleets of 1800 comprised entirely sailing vessels, while those of the present time are made up almost exclusively of steamers. The steamer is a much more efficient carrier than the sailing vessel, for obvious reasons In comparing the two types, the best authorities practically agree that at the present time the net tonnage of the steamer (net tonnage being the space available for cargo and passengers, excluding machinery, bunker coal, etc) should be taken at four times the net tonnage of the sailing ship. The table below, in thousands of tons, gives Mulhall's figures for 1800, and on the basis just stated the potential tonnage of shipping for 1900 and 1910, computed from Lloyd's Register for the years specified

	Potential Tonnage.		
	Mulhall	Lloyd's Register	
	1800	1900	1910
British	1,856	31,917	44,795
American	970	5,420	12,107
German	160	5,868	10,040
French	250	2,468	3,780
Norwegian	70	2,925	4,031
Various	730	12,492	22,056
Total	4,026	62,100	96,809

The ships of England, Germany, France, Norway and most foreign powers sail the salt seas, more than half the American tonnage for 1910 in the table above traversed the improved channels and fresh water of the Great Lakes In ten years the carrying capacity of the Great Lakes fleet has increased more than threefold

In a few years the Panama Canal will probably be open to navigation The trade by sea between the Atlantic and Pacific coasts of the United States is reserved to American vessels If reasonable advantage be taken of our enormous expenditure in constructing the canal, its opening to commerce will result in a rapid increase in American shipping Consistently with our treaties we are at liberty to provide that tolls on American merchant vessels passing through the canal either in domestic or foreign trade shall be paid from the treasury of the United States There are ample precedents for such legislation in acts of Congress and in the legislation of other countries in respect of their navigation through the Suez Canal. It now seems probable that even before the opening of the canal the Congress may pass a law allowing ships built abroad to be registered in the United States exclusively for trade with foreign countries and with the Philippines. Ships have not been built for that purpose in the United States for some years, and the domestic shipbuilding industry would not be materially affected thereby, as of late American capital seeking investment in maritime enterprises has bought ships built abroad and sailed them under foreign flags From such legislation the amount of anticipated benefit has been greatly exaggerated The Gulf of Mexico and the Caribbean Sea are thronged with steamers owned by Americans, but sailing under foreign flags Conditions of political unrest in Central American States, Venezuela, and recently in Mexico, have made it certain that were the opportunity offered, the owners of these fleets would seek American registry in order to secure at all times the protection of the flag In trans-oceanic navigation, however, such considerations do not obtain, and it is difficult to find any satisfactory inducement for the transfer of a foreign-built ship to the American flag in the face of the higher wages which indisputably prevail on American ships

It is a matter for profound regret that the United States has not carried to completion the ocean mail system undertaken twenty years ago The reasons for the establishment of a complete ocean mail system are much stronger now than they were at that time Alaska has been developed, we have acquired Hawaii, the Philippines and lesser Islands on the Pacific and Porto Rico on the Atlantic, and the highest statesmanship both here and in the republics to the south of us has interested itself In bringing about closer relations between the two Americas Sooner or later the establishment of such a system is as inevitable as was the building of our new navy Agitation for more than twenty years was needed to create a fleet of modern battleships, and an equal or longer time may elapse before an adequate ocean mail subsidy bill will be approved by Congress with certain results Of England's mail subsidy system some years ago President Hadley of Yale College wrote

"Its aims are political and not commercial It is a necessity for England to have constant communication with her colonies, and she has spent large sums for this object It is almost equally important for her to have an efficient naval reserve and transport service, and she has made her mail contracts one among several means toward this end"

These words apply with equal force to the necessities of the United States to-day Free ships for foreign trade and subsidies are not alternative or conflicting propositions, but independent methods of dealing with two different subjects

A Remarkable Ice Palace

THE use of ice for architectural purposes is an art that has been carried to a high state of perfection in northern countries, and some almost incredible feats have been accomplished in this curious branch of industry

Probably the most remarkable building constructed wholly of ice was the palace built on the Neva by the Czarina Anne of Russia, in 1739. The first attempt to construct this building was unsuccessful, as the slabs of ice were too thin, and the building collapsed in the first thaw Subsequently large blocks of ice were cut and squared with great care, and laid on one another by skilful masons, who cemented the joints with water, which immediately froze. The building, when completed, was fifty-six feet long, seventeen and a half broad, and twenty-one high. It was of but one story. The façade contained a door surmounted by an ornamental pediment, and six windows, the frames and panes of which were all of ice. An elaborate balustrade, adorned with statues, ran along the top of the façade, and another balustrade surrounded the building at the level of the ground. The side entrances to the inclosure were flanked with pillars supporting urns, the latter containing orange trees, whose branches, leaves and flowers were all of ice. Hollow pyramids of ice, on each side of the building, contained lights by night. The grounds were further adorned with a life-size figure of an elephant, with his mahout on his back. A stream of water was thrown from the elephant's trunk by day, and a flame of naphtha by night.

A tent of ice contained a hot bath, in which persons actually bathed. There were also several cannons and mortars of ice, which were loaded with bullets of ice and iron, and discharged.

The interior of the building was completely furnished, with tables, chairs, statues, looking-glasses, a clock, a complete tea-service, etc., all made of ice, and painted to imitate the real objects. A bed-chamber contained a state bed, with curtains, a dressing table with a mirror, pillows, bed clothes, slippers and night caps—all made of ice. There were ice candles, burning naphtha; and, most wonderful of all, an ice fireplace contained burning ice logs'—i e , blocks of ice smeared with naphtha and then kindled.

Wonders of Telephony

THE casual user of the 'phone who lifts off the receiver and talks to a friend miles away, has little idea of the wonders of telephony or of the labor necessary to maintain an up-to-date service

The "telephone laboratory" is one of the busiest places in the world It is here that the problems of telephony are worked out and means devised to improve and develop the system to meet future demands upon it.

Here any day one may see two experts in a room 15 or 20 feet wide and two or three times that length, talking with each other over circuits a thousand miles long The equivalent of twenty miles of cable is contained in a box no bigger than an ordinary traveling bag, and 600 miles of pole line is represented by the contents of another box not as large as a dress suit case, while the entire apparatus at the central office, so far as it affects the individual subscriber's telephone line, is compressed into a couple of square feet.

With this equipment and two standardized telephone instruments, conversations over hundreds of miles are carried on within the four walls of this laboratory, one of the workshops of the central engineering force of the system

Every detail of a long distance circuit from the subscriber's 'phone at one end of the line to that at the other end, with all the central office and overhead and underground construction that connects them, is reproduced with scientific exactness By these means new devices and apparatus are tested, proposed improvements investigated, and the scientific theories involved in transmission and operation worked out This may be done for the purpose of studying some minor bit of mechanism, of determining, for instance, the relative merits of two forms of the relay coils which automatically work the signals on the switchboard, or of learning the effect on a conversation of having one sort of equipment at one end of the line and another sort at the other end, or for any of a hundred other purposes

Rules for Memorizing the Strength and Density of Concentrated Acids

THE following mnemonic rules, republished from the *Zeit f ang Chemie* have been given by E H Riesenfeld for the relation between percentage composition, specific gravity and concentration expressed in grammes per liter

1 The per cent content of concentrated hydrochloric, nitric and sulphuric acids is equal to their molecular weight, while the concentration in gramme molecules per liter is equal to ten times their specific gravity This is brought out in the following table

Concentration	Baumé, Deg	Mol, Wt	Content, Per Cent.	Sp. Gr	Gm. Mols Per Liter
HCl	23	36	37	1 2	12
HNO_3	40	63	63	1 4	14
H_2SO_4	66	98	98	1 8	18

2 The percentage of aqueous hydrochloric acid is equal to 200 times the difference between its specific gravity and that of water, or in other words $p = 200\ (s - 1)$ This relation is shown in the appended table:

Sp Gr.	Content, Per Cent.	Sp. Gr	Content Per Cent.
1 01	2	1 10	20
1.05	10	1.15	30

The Only Way to Restore the American Merchant Marine

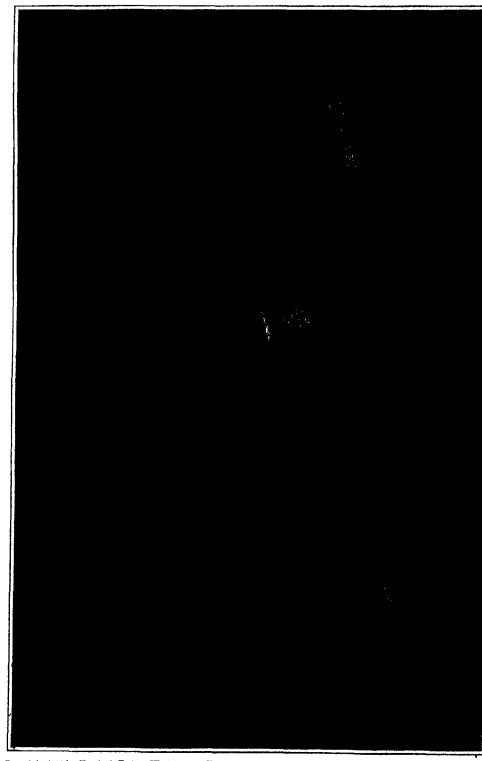
Why Preferential Duties are Better than Free Ships or Subsidies

By the Hon. William Sulzer, Member of Congress

WE all realize that there is a sentiment, growing stronger and stronger every day, throughout the country in favor of doing something to rehabilitate our merchant marine. This is patriotic, eminently proper and should be encouraged by every true American. It is unfortunate, however, that many well-meaning citizens, who desire to see our ocean carrying trade restored to our own merchant marine, have little knowledge of the best way to do it, or of the causes which gradually drove our shipping from the high seas and placed us finally at the bottom of the list of the world's maritime powers.

There is no man in this country more anxious and more willing to enact proper legislation to restore the American merchant marine than myself, but I want to do it honestly, I want to do it along constitutional lines, and I want to do it in harmony with that fundamental principle of equal rights to all and special privileges to none.

It is a fact—a most deplorable fact—and every man who has investigated the subject knows it, that we have less registered tonnage for deep sea carrying trade to-day than we had 100 years ago. In 1810 the United States, with a population of less than 10,000,000 inhabitants owned more registered tonnage for ocean carrying trade than the United States in 1910, with a population of over 90,000,000. The American deep sea tonnage in 1810 was over 1,200,000, and it is now less than 800,000, and what is worse still, it showed an actual decrease of more than 6,000 tons last year. In 1810 American ships, flying the American flag and manned by American sailors, carried over 90 per cent of our deep sea trade and a great part of that of all the countries of Europe. To-day we carry very little of our own trade, and practically none of other countries notwithstanding the fact that we should be the foremost maritime power in the world.



It is a sad commentary on our growth and greatness that more than nine-tenths of our once great and powerful deep-sea fleet has vanished, and not one new keel for an ocean going merchant ship is being laid to-day on either our Atlantic or Pacific coast while the vessels of foreign nations throng our ports and monopolize more than nine-tenths of all our import and export commerce.

The question of the hour is how shall we restore the American merchant marine? What shall we do to place our flag again on every sea? What policy shall we adopt to regain our ocean carrying trade and revive our shipbuilding industry? There are several policies proposed by those who desire to restore the American flag to the high seas and secure for our country its proper share of the world's ocean commerce, and, briefly enumerated they are as follows.

First—Ship subsidies.
Second—Free ships.
Third—Preferential duties.

Let me briefly discuss these proposed remedies in their order, stating as succinctly as I can, without prejudice, the merits and the demerits of each proposition, and I shall do so from a patriotic and not from a political point of view, because, in my judgment, the restoration of our merchant marine is purely an economic question based on patriotism, and rises superior to partisan considerations.

Let us come, then, to the first proposition, to wit, ship subsidies. In the light of the past, I think we can safely say that the American people are unalterably opposed to a ship subsidy raid on the Treasury. A subsidy is a bounty, a bonus, a gratuity, and it never has succeeded, and it never will succeed, in accomplishing the purpose desired. All history proves it conclusively. Wherever and whenever it has been tried it has failed. In my opinion, if a subsidy bill should pass it would not restore our American merchant marine or aid our shipbuilding industries. It is a waste of time to talk about ship subsidies. We might just as well pass a bill to pay a subsidy to every man who grows a bushel of wheat or raises a bale of cotton as to pay a subsidy to the man who builds a ship.

Copyright 1911 by Harris & Ewing, Washington, D. C.

HON. WILLIAM SULZER
Member of Congress. Author of the bill in Congress for preferential duties.

I am now, always have been, and always expect to be opposed to ship subsidies that rob the many for the benefit of the few. Ship subsidies do not build ships; they create ocean monopolies. Ship subsidies will not give workmen employment in American shipyards; the money taken without justification from the Treasury of the people will simply go to the men who own the ships now in commission.

Every scheme of this kind simply permits respectable corruption and benefits the few at the expense of the many. The principle of ship subsidies is inherently wrong, absolutely indefensible, and no man who understands the question can justify the policy in the face of the facts.

The taxpayers of our country, burdened now almost beyond endurance, are opposed to ship subsidies. They are opposed to any gift bill. They say no private business should be aided by direct grants from the Treasury. Ship subsidies are subversive of the eternal principles of equality, contrary to the theory of our institutions, of doubtful expediency, and at war with the spirit of the Constitution. Congress has no power to subsidize any trade, on land or sea, at the expense of the taxpayers of our country. Any attempt to fasten this odious system of ship subsidies on the legislative policy of the country is undemocratic, unrepublican, and un-American.

And now let us discuss the second remedy, to wit, free ships, by which I mean the right of an American citizen to build or buy a ship anywhere, give it the benefit of the American registry laws, and place upon it the American flag. To bring this about, all that is necessary to do is to repeal the prohibitive law, which is a blot on our common sense and a disgrace to our maritime intelligence; but this will never be done while the believers in protection for the sake of protection can prevent it, because they know it would be a death blow to their sacred doctrine. This policy of free ships has been advocated for years by many able and patriotic men who thoroughly understand this shipping question and deplore the loss we are sustaining every year by reason of the elimination of our merchant marine.

What a spectacle is presented when we realize that by virtue of our existing navigation laws the American who builds or buys a ship in a foreign country is an outlaw—prevented from giving the vessel American registration and compelled to sail the ship under the protection of a foreign flag.

There are, of course, several other objections urged against free ships, but I shall not go into details now and discuss them because I believe it will be impossible to pass a free ship bill at present through the Congress of the United States.

Now let us take up the third proposition, namely, preferential duties in favor of American-built ships and against ships flying the flag of a foreign country. My bill introduced in the congress provides for this, and I hope to see it pass ere this Congress finally adjourns. This was the policy so successfully in operation in this country up to 1828, when, to please foreign interests, the law was suspended, and from that day to this our prestige on the high seas has been declining until it is less to-day than it was a century ago.

The true friends of our merchant marine believe that if this policy of the fathers was restored it would revive our oversea carrying trade, and in a very few years build up our ship industries so that we would again secure our share of the ocean commerce of the world and save millions and millions of dollars that we pay annually to foreign shipowners. In reading the report of the Merchant Marine Commission, I observe that several of the largest shipbuilders testified that they formerly believed in subsidies, but had changed their opinions and now advocated preferential duties.

There seems to be but one objection, so far as I can learn, to a return to preferential duties, and this objection comes from the advocates of ship subsidies, who declare that we have commercial treaties with foreign governments containing the favored-nation clause, and in order to inaugurate the policy of preferential duties it will be necessary to change our commercial treaties, and this cannot be done without giving these favored nations one year's notice.

This objection, however, is more apparent than real, for there is no doubt the change could be made if this Government wanted to make it, and a year's notice to bring it about would cause no great delay, especially when we consider that nothing has been done for our deep sea shipping in more than a quarter of a century.

If we desire to change our commercial treaties with these favored nations, we have a perfect right to do so, and no nation can object. If there be retaliation, two can play at the same game, and our trade is more important to other nations than their trade is to our country. As I have said, many citizens and several distinguished members of Congress who have given this subject much thought and consideration believe that preferential duties will effectually solve the problem in the most feasible and practicable way.

It is my candid opinion, and I have no hesitancy in saying so, that if we had continued the policy of the fathers, and not suspended our early preferential duty laws, we would to-day be the greatest maritime nation in the world, and our flag would be on every sea and our ships would be carrying the commerce not alone of our own country, but perhaps half of that of all the other great nations of the world.

In this Congress I have again introduced my bill for preferential duties. It is a short bill and reads as follows:

A BILL

TO ENCOURAGE THE MERCHANT MARINE AND AMERICAN COMMERCE, AND FOR OTHER PURPOSES

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That a reduction of the duty of five per centum ad valorem of all of the customs duties now or hereafter imposed by law shall be allowed on all goods, wares, and merchandise imported into the United States in vessels of the United States. The said reduction in duty herein provided for shall not apply to goods, wares, and merchandise not of the growth, production, or manufacture of countries contiguous to or bordering upon the territory of the United States when imported into the United States by land transportation or land vehicles or conveyances through or from ports or other places of countries bordering upon the United States, if the same shall have been brought to such ports in vessels not of the United States. And said reduction of duty shall not apply to all cases where goods, wares, or merchandise are transshipped or transferred from a foreign vessel port, or place to a vessel of the United States for the purpose of evading the provisions of this Act.

SEC. 2. That the master, agent, or owner of any registered vessel of the United States shall be exempt from the tax of *four dollars for every alien* entering the United States on such vessel prescribed by section one of the Act of February twentieth, nineteen hundred and seven entitled "An Act to regulate the immigration of aliens into the United States."

SEC. 3. That the President shall have power, and it shall be his duty, to give notice within ten days after the passage of this Act, to all foreign countries with which commercial agreements have been entered into making any provision or provisions which are in conflict with sections one or two of this Act of the intention of the United States to terminate such agreement at a time specified in said notice, which time shall in no case be longer than the period of time specified in such agreements respectively for notice for their termination. *Provided*, That until the expiration of the period when the notice of intention to terminate hereinbefore provided for shall have become effective, or until such date prior thereto as the high contracting parties may by mutual consent select the terms of said comercial agreement shall remain in force.

SEC. 4. That all Acts and parts of Acts in conflict with the provisions of this Act are hereby repealed, and that, except as provided in the first and second sections, hereof, this Act shall take effect and be in force from and after its passage.

To the champions of subsidies, which at best are only a temporary relief, I reply that we never can help our shipbuilding industries and restore our merchant marine unless we adopt the policy of free ships or discriminate in some way in favor of our own ships and against foreign ships. The fact is that we discriminate now by law against our own ships in favor of foreign ships. My plan is simply to reverse the situation. I sincerely believe that if my bill for preferential duties were enacted into law, the United States in a few years would become the mistress of the seas, and American ships built in our own shipyards would do all our own ocean commerce besides a great part of the deep sea carrying trade of the other countries of the world, without taking a dollar out of the pockets of the taxpayers.

Let me say in conclusion, that the policy I propose is not a makeshift. It is not new—having been the law of our country from 1792 to 1828, when it was suspended—and that suspension was one of the greatest political blunders in all our history. It is not a temporary expedient. It is permanent. It has been tried and not found wanting. It is the only way to restore the American merchant marine. Adopted again as our policy and upon the statute books, it will never be repealed, but, on the contrary, speedily restore our ocean carrying trade, revive our shipbuilding industries, give employment in our shipyards to thousands and thousands of men in all parts of the country, bring about an era of prosperity such as we have never known before in our shipping trade and deep sea commerce, place our flag on every sea and in every port, and make our seamen what they were in the historic days of the republic—the pride of America and the masters of the ocean highways of the world.

Smallpox in the United States in 1909

WHILE the sentimentalists are shouting "Anti-vivisection" and "Anti-vaccination" at us, the scientists are "sawing wood." A compilation from the State and city health reports for 1909 pertaining to smallpox has just been published by the Public Health and Marine Hospital Service. Complete reports are available for only twenty-six States and the District of Columbia. In all of these and in most of the other States the disease was prevalent during 1909.

The States showing the largest number of cases (over 1,000), as well as the rate per 100,000 of population, are shown in the following table.

	Number of Cases	Cases per 100,000
Kansas	2,197	131.67
Illinois	2,135	38.31
Utah	1,854	507.11
North Carolina	1,733	79.45
Oklahoma	1,434	90.41
Minnesota	1,430	69.41
Louisiana	1,409	(Incomplete)
Indiana	1,363	50.74
Ohio	1,328	28.14
Wisconsin	1,208	52.14
Michigan	1,175	42.38

After Utah, with the exceptionally high rate of over 507 cases to 100,000, the highest rate was reported for Montana, 187.46 per 100,000 of population; then came Kansas and Oklahoma. The best showing was made by Florida, Connecticut and New Hampshire, which reported, respectively, 3, 3 and 2 cases.

The disease in 1909 was of a comparatively mild type, the death rate averaging less than 1 per cent. This is very low when compared to a mortality of from 18 to 28 per cent, which was the record in European outbreaks in recent years.

The importance of vaccination was again demonstrated by the outbreak of the disease in Yorkville, S. C., during March and April, 1909. The first case was that of a man of 32 years, unvaccinated, who died within two weeks. Fifteen persons had been exposed to infection from this case, of these only two had been vaccinated, one five years previously and the other forty-four years. These two nursed the patient for ten days, and neither contracted the disease. Of the other thirteen, eight died. Vaccination had been applied as soon as vaccine could be obtained; it was effective in five cases. And these were the cases that recovered. In the meanwhile all the other inhabitants of the town were vaccinated—about 400 in all; and although the thirteen persons who had contracted the disease from the first patient furnished seven centers for further infection, an epidemic was entirely prevented, only one other case developing, and that of a mild type.

The compilation, prepared by Assistant Surgeon-General John W. Trask, includes two maps of the United States, one showing the number of cases in each State and the other the rate per 100,000 for each State.

The Gem Production of the United States

THE total value of the precious stones produced in the United States in 1909 was $534,380, an increase of $118,317 over 1908. The increase is due, according to a press bulletin of the United States Geological Survey, to larger outputs of turquoise, tourmaline, variscite, chrysoprase, californite and kunzite. The production of beryl, garnet, peridot and topaz showed a decrease in value. The output of turquoise matrix and turquoise amounted to over 17 tons, that of variscite to over 3½ tons, and that of tourmaline to over 2½ tons. A beautiful new gem, benitoite, resembling the sapphire in some respects, has been found in San Benito County, Cal. Californite is compact, massive vesuvianite and resembles jade in hardness, texture and color, and should be a popular native gem. Chrysoprase has also been mined in California.

Deposits of turquoise have been worked in Arizona, California, Colorado, Nevada, New Mexico and Texas. Turquoise is generally found in arid or desert regions, where mining is difficult. New Mexico, California and Arizona were formerly the chief sources of turquoise, but during the last few years Nevada has been one of the principal producers. Variscite, like turquoise, is generally found in desert regions. The output formerly came from Utah under the names of utahlite, chlor-utahlite, amatrice and variscite, but since 1908 a number of deposits found in Nevada have contributed to the production. Recently there has been an increased demand for this gem in the matrix.—*The Engineering and Mining Journal*.

A Forest Service Circular on Colombian Mahogany

THE forester, the lumber dealer, and the wood user have long been painfully conscious of the prevalent tendency on the part of wholesalers to substitute one wood for another of better grade and quality. Even the importer of foreign woods will be surprised to learn from authoritative statements that more than 50 per cent of the bulk of the woods now shipped into this country as mahogany is not mahogany at all, but in the majority of cases such substitutes are much inferior woods. In a circular entitled "Colombian Mahogany, Its Use as a Substitute for True Mahogany," just issued by the Forest Service, Mr. George B. Sudworth, Dendrologist, and his assistant, Mr. C. D. Mell, call attention to the fact that fully 20 entirely different woods are now being sold as mahogany. They inform the readers that the Colombian mahogany (*Carapa guyanensis*, Miers), a wood from Colombia, has been sold in this country and abroad for more than thirty years as the genuine mahogany (*Swietenia mahagoni*, Jacq.). The circular is written with the greatest regard for scientific accuracy and thoroughness but in such a way as to interest the average intelligent reader. It contains excellent information for the wood user, but it embodies much interesting reading for the botanist as well. The first part of the publication gives the botanical characters of the tree yielding the Colombian mahogany and compares them with those of true mahogany. To the botanical description is added a general consideration of the source of supply, quality, chemical and physical properties of the wood, and its uses. The circular describes very fully for purposes of identification by the unscientific reader the woods of these two species, treating with special fullness the minute structural characters of the wood of the Colombian mahogany. The rest of the circular is devoted to a clear presentation of the difference in structural characters between Colombian and true mahogany. In these days of substitution of lumber, this circular has a good claim to popular favor among mahogany consumers and buyers of furniture. It is a valuable contribution to the scientific knowledge of economic woods and the material should be useful to readers unfamiliar with the subject. The circular is profusely illustrated with numerous excellent black line drawings prepared by one of the best trained artists in the country.

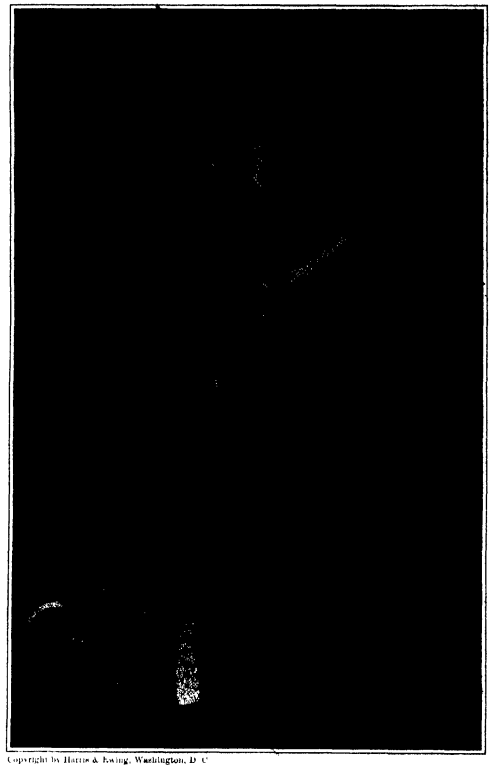
The Shame of Eating

IN some primitive tribes, eating is regarded as something to be ashamed of. Karl von der Steinen, the celebrated explorer, was looked upon as a very ill-bred person by the natives of South American forests because he ate in the presence of others. The original ground of the shame associated with eating is a fear of evil spirits. The feeling of shame is not inborn in mankind and it assumes very different forms in different regions. A remnant of the superstitious fear connected with the act of taking food appears in the ejaculation "Prosit!" which, in Germany, is religiously uttered by the companions of a man who is about to take a drink. This Latin verbal form, the general meaning of which is "may it be beneficial" is now understood simply as the expression of a wish that the drink will agree with the drinker's constitution, but it originally connoted the hope that the drink had not been bewitched.

These statements are made by a writer in *Hygeia*, who adds that the division of labor between men and women was originally, and still is among primitive peoples, much more sharply defined than it is at present in civilized countries. This sharp division of labor brought about a separation at meals. The Eskimos have separate dishes for the two sexes, and a man would be deeply ashamed to eat with women. It is possible that the decoration of plates and cups was designed to serve as a counter-charm, as well as an ornament. When the fear of demons had passed, the custom of eating in private which that fear inspired was sometimes maintained by force of habit, so that eating in public came to be regarded as a shameful breach of good manners.

Our Merchant Marine and the South American Republics

First-class Ships as an Aid to Closer Commercial Relations



By the Hon. John Barrett, Director-General of the Pan-American Union

THIS is not an argument for or against so-called subsidies. It is a simple discussion of the subject of steamship connections between North and South America, without reference to partisan views or political policies. In the first place, there stands out a fact which is pre-eminently true: First-class steamship facilities for the exchange of trade products and the carrying of passengers and mails are just as necessary between countries separated by the high seas as first class railroad facilities for similar purposes between countries and states separated only by boundary lines. The better the railroad facilities the greater the trade exchange, the more travel, and the more frequent the mails. Correspondingly, the better the steamship facilities the greater becomes the commerce, the more general the travel and the more frequent the communication between countries and peoples widely apart.

Before developing further this subject in its relation to Latin America, one or two points should be cleared up. The statement is being continually made by those not familiar with the situation that trade between the United States and its sister republics can not be built up until it enjoys greatly improved steamship service. And the common supposition seems to be that not only passenger but freight lines are lacking to take care of the possible business. While it is true that there are few passenger or freight boats flying the American flag, there is a large fleet of vessels flying foreign flags and conveying the traffic back and forth between North and South America. The high class fast passenger vessels of any flag running to the southern part of South America are indeed limited in number compared to those which ply between that part of the southern continent and Europe, but the number of freight vessels running from New York city, for example, to all sections of Latin America is sufficiently large, and their sailings are frequent enough, to take care practically of all the freight that is offered, and for the most part at rates fairly competitive with those of Europe. The only adverse criticism from the standpoint of the United States that can be made in regard to this situation, is that very few of these vessels are under the American flag, although there is no security that, even if they were, the rates would be any lower than they are at the present time.

Surveying the field from the north and working south, we find the conditions generally much better than the average man supposes. Every important port on the Gulf and Caribbean coasts of Mexico, the Central American republics, Panama, Colombia and Venezuela in northern South America, Cuba, the Dominican Republic, Haiti, and the West Indies can be reached by the vessels which provide abundant freight space and fairly good passenger accommodations and in some cases the latter are excellent. Vessels are constantly running back and forth between these ports and New York city, Boston, Baltimore, New Orleans, Mobile and Galveston. One line has recently made such improvement in its passenger arrangements out of both New Orleans and New York that there has been a gratifying increase in the number of passengers it has been carrying to and from ports on the Caribbean and the Gulf of Mexico.

Considering the east coast of South America, under which are comprehended Brazil, Uruguay and Argentina and such well-known ports as Rio de Janeiro, Montevideo and Buenos Aires, it can be noted that there are abundant freight facilities for all the business that is offered either way. The passenger accommodations on some of these vessels have been greatly improved during the last two years, and still more notable advancement is to be made in the future. It is no longer necessary that the traveler, who wishes to be comfortable, should go to the east coast of South America by the way of Europe, if he is not too anxious to sail without any delay. In other words, if he is willing to adapt his sailing to certain vessels, he can, at least once or twice a month, get very good boats direct from New York to Rio de Janeiro and Buenos Aires. It must be admitted, however, that, if he is in a hurry, he can usually do better by proceeding directly to Europe and taking one of the fast English, German or French steamers.

Copyright by Harris & Ewing, Washington, D. C.

HON. JOHN BARRETT
Director-General of the Pan-American Union.

Considering the west coast of southern North America, that is of Mexico and Central America, and the republics bordering on the Pacific of South America, we find that there are fair facilities both for passengers and for freight from Panama south to the ports in Colombia, Ecuador, Peru, Chile, and, via both Peru and Chile, to Bolivia. Steamers leave at least once a week from Panama for such ports as Guayaquil, Callao, Mollendo, Iquique and Valparaiso. There has been much improvement of late in these routes, new steamers having been put on by the lines operating, while others are to be placed in commission as soon as constructed. The service between the Pacific coast of the United States and the west coast of Mexico, Central America and Panama is somewhat limited, but seems at the present time to take care of nearly all the business that is offered. There is no question that these lines will be improved by the time the Panama Canal opens, and several companies, planning to enter the field, are now only awaiting developments in connection with canal tolls to decide what they will do.

What I desire to see, as an international officer, is not only more steamers put on flying the American flag, but more flying any flag. The greater the competition and the more vessels there are, the greater will be the effort of business interests to get into the field. The buying and selling between North and South America will grow with better steamship facilities, no matter what the flag, just as trade grows on land between different States and citizens with better railroad connections between them. Perhaps I am not as strong as I should be for special laws in favor of the shipping of the United States, because in my capacity as a Pan-American officer I want to see the countries of Latin America, like Mexico, Peru, Chile, Argentina and Brazil, putting on vessels which will ply between the ports of their countries and those of the United States. I think it would be unfortunate to discriminate in shipping tolls through the Canal in favor of the vessels of the United States unless they are engaged in the coastwise trade. In other words, I believe it would be a cardinal error to allow a vessel flying the United States flag plying, for example, between the United States and Chile, to have any advantage in canal tolls over the vessel flying the Chilean flag which might do business between Chile and the United States. It is to be hoped that there will not be any legislation which would discriminate against ships of other nations going through the Canal and engaging in international commerce. Such action of the United States might naturally be considered by the twenty countries lying to the south of us as being adverse to international comity and the development of friendly relations.

Viewing some practical phases of the situation, we can not overlook the necessity of having the best arrangements for the exchange of mail. The more frequently and the more rapidly letters, papers, reports and other data can be exchanged between the United States and all the countries to the south of it, the more rapidly will trade develop. The European countries have benefited enormously from excellent mail facilities with Latin America, and the business men of the United States will find when this handicap is overcome that a great increase in their trade will result. It must also be borne in mind that there is no better way of developing trade than the mutual acquaintance of both buyers and sellers. If the steamship facilities between the United States and Latin America are so improved that the average business man and tourist of the latter can travel to and from the former with the same speed and comfort that he can travel to and from Europe he will go to the United States, get acquainted with its people, its institutions, its business men, its conditions of trade, and will both purchase and sell there to a far greater degree than ever before. The importers of Latin America, enjoy combining business with pleasure, and, in seeking the combination of both, they find the steamships which take them to and from Europe offer greater inducements than those which take them to

and from the United States, although of late, in response to the efforts of one company to better its service, there has been a notable change in favor of visiting the United States. The conclusion must be that the more this service improves the more will Latin Americans come to the United States. Correspondingly, a large element of American exporters and business men who now visit Europe or Asia will go only too readily to Latin America when they realize that they can travel in comfort. The knowledge that the facilities are already much better than they were formerly has resulted in a considerable increase of Americans going directly to Latin America from New York, New Orleans, and San Francisco, and there are indications that the travel next year will be far larger than ever before.

As supporting the contention that improved steamship service will not fail of appreciation by the business interests of North and South America, it is well to bear in mind some of the present conditions of Pan-American trade The great majority of the people of the United States do not realize how extensive already is the exchange of products between North and South America, and how rapidly this business has developed during the last ten years Too many manufacturers, merchants, importers and exporters, who have not studied the field and the facts, are inclined to pooh-pooh its importance and opportunity, and therefore make no effort to enter it. The truth is that the export and import trade of the United States with the twenty Latin-American countries lying to the south of it has grown with remarkable and gratifying rapidity during the last ten or fifteen years. If it has been able to make this advance under what are generally considered adverse steamship conditions, it must be admitted that it will make far greater progress in the future, when these facilities are extended and improved

The total annual value of exports and imports exchanged between the United States and its sister republics approaches now six hundred and fifty millions of dollars. Fifteen years ago it did not exceed two hundred and fifty millions of dollars This means a remarkable growth of four hundred millions of dollars in little more than a decade This, in turn, is a percentage not surpassed by the trade of the United States with any other section of the world, and in startling comparison with the trade of the United States with Asia, which has practically stood still, and, in the case of some countries, has actually decreased

The evidence that this annual commerce of six hundred and fifty millions of dollars has an opportunity of expansion is shown in the fact that the total foreign trade of Latin America exceeds now two billions of dollars per annum The share of the United States therefore is greater than one-fourth—certainly a condition against which there can be little complaint when we consider the activity of the business interests of Great Britain, Germany, France, Belgium, Holland, Spain, Portugal, and Austria-Hungary

As a specific illustration of the value of Pan-American foreign commerce, the foreign trade of Argentina can be cited Last year this exceeded seven hundred millions of dollars, an average of nearly one hundred dollars per head, and larger than the foreign trade of either Japan or China

In studying these figures of Latin-American trade, it is interesting to note what may be the opportunity for steamships plying through the Panama Canal The five countries which form the western or Pacific slope of South America, including Colombia, Ecuador, Peru, Bolivia, and Chile, last year bought and sold with the rest of the world a commerce valued in excess of three hundred millions of dollars If they can conduct a business of this size, despite their isolated position, they should be able to double it within a few years after the opening of the Canal, and the share of the United States in view of its new proximity brought about by the Canal, should grow more rapidly than that of any other country There will be a demand for an increased fleet of vessels to run directly between the principal ports of the Atlantic and Gulf coasts of the United States and those of the western shore of South America, which reaches for five thousand miles from Panama to Punta Arenas There will also be a demand for more vessels to communicate through the Canal with the west coast of Central America and Mexico, which reaches for nearly three thousand miles from Panama to San Diego This section of Latin America, that is, the portion bordering on the Pacific Ocean, now conducts a foreign commerce in excess of one hundred millions of dollars per annum—a total which will double within five years after the Canal is opened if there are satisfactory steamship facilities

The Present Status of Cancer Research

By Dr. Moyer S. Fleisher, Barnard Free Skin and Cancer Hospital, St. Louis, Mo.

IT is now scarcely ten years since the experimental investigation of the cancer problem was first entered upon, and therefore we are to-day only on the threshold of a true and definite knowledge regarding cancer While for many years, indeed, since the first half of the last century, the problems of cancer, its origin and nature, have occupied the thoughts of investigators, it was not until the early part of this century, under the stimulus of successful experimental work carried out by Loeb (an American investigator) on rats, and later, though independently, by Jansen (a Danish investigator) on mice, that general interest was awakened in this subject.

Before this time almost all investigation concerning cancer had been limited to the microscopical examination of these tumors and by means of this examination cancers had been classified, and there developed as a result of these investigations a multitude of purely hypothetical theories regarding the cause of cancer.

It may be advisable to pause here and define what a cancer is A cancer is a mass of cells, whose origin is from the cells which normally constitute our bodies The structure of the cancer cells is similar to that of the normal cells These cancer cells, unlike normal cells of the adult body, have the power of very rapid growth or proliferation In the course of this rapid growth the relationships of the cancer cells to one another, or to neighboring cells, deviate to a greater or less degree from those of their parent cells. They not only break through their normal boundaries, and invade and destroy the surrounding normal tissue, but also individual cells or masses of cancer cells may be carried in either blood or lymph vessels, to parts of the body distant from their site of origin, and may there continue their rapid growth and constitute secondary cancers, which are spoken of as metastases

Under the general term of cancer we group all abnormal malignant growths which have the above characteristics; however, there are two distinct types of cancer. It must be clearly understood that the body is composed of many different kinds of cells, and that various groups of specialised cells form what we call organs. It is, however, possible to group these cells under two headings; the first are called epithelial cells; under this group are included the cells lining the alimentary tract, and the air passages, the superficial cells of our skin and the more important cells of the glands within our bodies. These epithelial cells give rise to a type of cancer which we call carcinoma. The second type of cells, which form the supporting and connecting structures for the epithelial cells, are called connective tissue cells, and give rise to a type of cancer called sarcoma.

During the years that our knowledge of malignant growths was being obtained only by means of the microscope, various theories were advanced to explain both the origin of and the phenomena connected with cancer. The theories which were advanced may be roughly divided into two groups

In the first of these the cause of cancer was said to be a pre-natal influence on either single cells or groups of cells Thus Cohnheim believed that during the time of embryonic development groups of cells were separated from their normal relations within the developing body, and, until some stimulus or impulse set them into activity, these groups of cells remained quiescent When once set into activity they again took on their embryonic quality, namely, power of rapid proliferation, and now developed as a cancer

While this theory serves to explain at least in part the origin of certain tumors, it fails to explain the origin of the true malignant tumors which we speak of as cancers. Ribbert holds that during the pre-natal period, or during the adult life, cells may be split off from their usual surroundings, and now take on the power of unchecked growth which we may consider as one of the characteristics of cancer

In the second group are those theories in which the cause of cancer is supposed to be an acquired abnormality, a change within the cells of the adult body These changes are supposed to be represented by chemical, physical or structural variations of the cells, or again the cells are supposed to have taken on new functions or activities

While these theories might serve to explain the origin of cancer from individual cells or from groups of cells in the body, they fail to point why these cells acquire the qualities which we associate with cancer Many theories were therefore advanced to explain why either quiescent embryonic cells or even normal cells should suddenly take on the power of unlimited growth. Various investigators offered suggestions that the structure of cells was changed or influenced in certain ways, but none of these hypotheses were supported by definite experimental proof

It is only since it was first learned that cancer could be transmitted from one animal to another that our knowledge of this disease has been obtained by experimental means.

It has been known for many years that the lower animals developed cancers which were similar to those seen in human beings In certain kinds of animals cancers appeared more frequently than in others, and it was noted that in rats and mice may cases of spontaneous cancer occurred The term spontaneous cancer is used here in order to distinguish the cancers which arise *de novo* from the "inoculated" cancers, produced by grafting a portion of a spontaneous cancer on a normal animal The knowledge that a spontaneous cancer can be inoculated into many series of normal animals forms the keystone of experimental cancer research.

In transmitting cancer from one animal to another some of the cells of a cancer are grafted on a normal animal (usually in the loose tissue under the skin); these implanted cells of the first animal grow, divide and multiply rapidly, thus we have growing in the second animal a cancer composed of the cells of the first animal It must be distinctly understood that the cancer in the second animal is in reality composed of cells of the first animal and the cells of the second animal, as a rule, take no part in the formation of the cancer This inoculated cancer may then be transmitted to a third, fourth or even an unlimited series of animals, so that the cancer cells of the first animal may be transmitted through many generations of animals and may be kept alive long after the death of the first animal

The experimentation on animals has as yet not brought any definite results as to what may be the cause of cancer, although some very suggestive and unexpected facts have been discovered

What role heredity may play in either development or tendency to development of cancer is as yet uncertain, and the relatively small number of experiments which have so far been carried out in this line are only suggestions of future possibilities It has been noted that within a relatively short period of time three cases of a rare kind of cancer developed in one family of rats It seems more likely that these cases were due to some heredity factor than that they were due to infection As yet no systematic and extensive work has been carried out which allows of any generalization regarding the influence of heredity We know, however, that heredity plays a part in transmitting certain qualities which are favorable or unfavorable to the growth of transplanted tumors

For many years efforts have been made to show a causal relationship between micro-organisms and the development of cancer, and thus to prove that cancer is of an infectious nature, as diseases such as typhoid fever, diphtheria or tetanus

Certain statistical studies which show the prevalence of cases of cancer in certain districts, the occurrence of epidemics of cancer cases, or the repeated occurrence of cancer in certain houses, would seem possibly to point to such an origin, but on the other hand, in these cases, heredity and various other factors which must be taken into consideration cannot be excluded

It has been noted in a few cases that when animals were inoculated with a certain kind of cancer (in the majority of cases with carcinoma), there developed in the inoculated animal a second kind of cancer (a sarcoma) One may here consider that the cells of the inoculated cancer have carried the cancer parasite which has then exerted its influence on the second class of cells It is of course impossible to exclude the suggestion that the carcinoma cells may have acted as an irritant, and thus led to the development of a sarcoma from the neighboring cells

Many investigators have attempted to demonstrate specific parasites as the cause of cancer Bacteria, yeasts, and even mites have been cultivated from

(Continued on page 58.)

The Merchant Marine as an Auxiliary to the Navy

Navy Would Need Some Nine Hundred Merchant Vessels to Draw from in Case of War

By T. G. Roberts, Naval Constructor United States Navy

IN order to bring home to our people a realization of the true importance of the question of providing an adequate merchant marine, what force of words of arguments, or what array of facts and statistics are necessary, beyond the multitude already available that have but recently fallen upon unheeding minds amid unpropitious times?

A navy is not fully complete without those auxiliary vessels which only a numerous merchant marine can supply and a healthy merchant marine is the greatest need of this country to-day After the outbreak of war merchant ships cannot be improvised any more than battleships A nation that would pretend to be a world power could not hope actually to achieve such a position while neglecting those very instruments without which potentiality cannot possibly be maintained Aside from the lack of that instrumentality for trade which a merchant marine supplies, it is inconceivable that a country as great and rich as ours, with a government so liberal and enlightened could blindly neglect a source of sea power so essential, if we are to avoid in the event of war a possible defeat upon the sea, with the Philippines, the Panama Canal and the Monroe Doctrine at stake—a defeat that would not only cost us a great loss of prestige, but would be all but irretrievable in effect When the actual cost of providing an adequate merchant marine is considered not over $15,000,000 a year—it is all the more incomprehensible that we should neglect that balance of sea power now standing between us and an effective readiness and at the same time thereby contribute to foreign shipping companies the profits on carrying annually about $3,000,000,000 worth of imports and exports, at a cost of something like $300,000,000 a year, and furnish them with the trade to keep them in existence, with their vessels available to foreign governments, through foreign subsidies, to be used against us upon the outbreak of war Thus, in the item of merchant marine auxiliaries, we have not only handicapped our sea power doubly, but our merchant shipping has also become the laughing stock of all the world and the butt for jokes of the sailor men of all nations.

A Contrast in Preparedness.

At the outbreak of our Spanish war we had practically no naval auxiliaries, but Congress immediately voted $50,000,000 for the national defense Of course this money went for almost everything immediately or remotely connected with the prosecution of the war, all the way from the mobilizing of the army to the purchasing and fitting out of auxiliaries for the navy About one hundred merchant and other vessels were purchased and fitted out as naval auxiliaries, of which over half consisted of yachts and tugs Many owners showed the patriotic willingness to let the government have their vessels, but the figures at which they went were characteristic of the phenomenal increase in the stress of war times in the values of articles which a government must have, a condition which has grown proverbial in history Just how much these yachts and tugs and second-class merchantmen contributed to the victory is difficult to estimate, but it is safe to say they could not have filled the vacancy caused by the absence of an adequate merchant marine in case the war had been extended across seas, or in the case of any material resistance from the Spanish fleet, which by its predestined collapse rendered the naval auxiliaries a question of minor importance How different with the merchant marine of Japan in the late Russian war' The following quotations were taken, with approval by the Merchant Marine Commission from the *Nautical Gazette* of January 26th 1905, containing an editorial from the *Japan Daily Mail*, relative to the steamship lines We read that "despite the disadvantages to which the Nippon Yusen has been put by reason of the war, the company has been able to pay its shareholders a dividend of 12 per cent The *Japan Daily Mail* says 'We cannot dismiss the subject without noting the situation in which the country would have been placed had the outbreak of war found it without the splendid transport facilities by the Nippon Yusen Kaisha's fleet In the piping times of peace unreflecting persons are apt to look askance at the great shipping companies which received a substantial measure of state aid and show enviably prosperous balance sheets But the truth is that such companies are just as essential to the safety and independence of the empire as are its army and its navy Without them, indeed, the army's field of potentiality is strictly limited to domestic territories, and in Japan's case it may be truly said that did she not possess the Nippon Yusen Kaisha she would have to submit tamely to compulsory exclusion from the continent of Asia, and to see Manchuria and Korea pass finally under Russian sway' Americans as a rule have admired and applauded Japan in her endeavor to rise to a position of strength as a modern nation. That her wisdom in creating a merchant marine has been so well justified in the present war should be a cause of congratulation. The United States can take a lesson from Japan's experience"

Of our ten foreign-going merchant vessels flying the American flag, only the four of the American Line have the benefit of mail subsidies under the law of 1891, and are available for naval auxiliaries The coast-line shipping is absolutely protected by laws practically prohibiting foreign vessels from participation, the rates being determined from competition with the railroads, and so, are absolutely independent of and incomparable with the foreign ocean rates. Though fully protected by law, but not by subsidies, these coast steamers are under no obligation to the government, and are not necessarily available for use as auxiliaries in time of war.

The General Board of the Navy Department, in 1905, responding to an inquiry from the Senate relative to the number of naval auxiliaries needed from a merchant marine, reported that, at that time, with the twenty-seven battleships then in prospect and the other ships available, the navy would need 171 auxiliaries to be drawn from the merchant marine in order to go to war properly With respect to this number, the board said' "In order to be sure that this number of vessels would be available for immediate purchase or charter by the Navy Department at the outbreak of war, the number of American-owned merchant vessels of each type should be largely in excess of the number here given, as some vessels would be abroad when needed, some under repairs, and some should be left for carrying on their regular commercial runs and as a reserve from which to draw in case of necessity . . . Another benefit which would accrue to the navy from a large fleet of American-owned vessels would lie in the large number of experienced sea-going men, engineers, and firemen accustomed to marine engines and boilers, who would form a valuable reserve from which to draw the men for manning the auxiliaries"

Supposing we had a merchant marine adequate for us to draw, say, one-fifth for immediate purposes, that would require a total merchant shipping of 855 vessels We have four now available and might be able to purchase, say, 100 vessels of the smaller classes, as in the case of the Spanish war It will thus be seen how far we are from possessing the auxiliaries absolutely essential to prosecute a foreign war In the event of such war the forty-nine colliers under foreign flags that supplied the fleet with coal during their voyage around the world would be unavailable by the mere operation of the laws of neutrality, and their places would be supplied by a vacancy which would strike our fleet with such force and such emphasis as would cause the American people to wake up and indulge in somewhat belated serious reflections.

In the event that troops should have to be transported across the seas the need of suitable vessels for army transports would be even more imperative than the naval auxiliaries. In 1905 the Army War College reported for the information of the Merchant Marine Commission that, to provide for an expedition of two divisions from either coast, an aggregate of 228 vessels, available in fifteen days, on both coasts, would be required If such a levy should call into immediate service say one-fifth of our imaginary merchant marine, that would indicate a merchant marine of 1,140 vessels to draw from I have said one-fifth at the first draw, because the merchant marine would have to supply additional vessels for subsequent needs in numbers depending upon the duration of the war and the casualties; and, furthermore, because no country expects to divert its entire merchant marine to the purposes of war, but of course plans to carry on its commerce with other nations during the war. Adding the 1,140 vessels necessary to supply the army needs to the 855 or navy needs, makes a total of 1,995 vessels of suitable size and speed which our merchant marine should contain. These figures are liberal, and provide an ample supply, and might be reduced to a minimum of one-fifth, or say 400 vessels, based on the assumption that the first expedition would be sufficient, and that all these vessels would be positively available to the government for war purposes, and that our corresponding commerce should cease during the war Comparing this minimum with the four merchant vessels now available, plus the few transports belonging to the army and the limited number of auxiliaries belonging to the navy, we find ourselves poor indeed.

The Foreign Shipping Interests.

Such a pitiable condition is all the more grievous from the outlook toward remedial legislation, and when we contemplate the enlightened but ineffectual efforts that have been expended now these seven years past with only a retrograding effect, we are torn with conflicting emotions—on the one hand with solicitude for the future preservation of our as yet untarnished national escutcheon; on the other hand with admiration for the foreign shipping interests, and the power and influence they have been able to wield so effectually in a country foreign to their own. Out of the congressional revelations of last year it developed incidentally that the foreign shipping interests control in the main practically all the commerce between this and foreign countries, both on land and sea, by rail and steamer, and that this control is exerted by a gigantic trust, with headquarters in Germany, that kills competition by Standard Oil methods. It is understood the government has entered suit in the Court of Equity under the Sherman anti-trust law against this monopoly in the manipulation and control of the passenger business, and the foreigners have taken the ground that this government has no jurisdiction over a foreign corporation The recent decision of the Supreme Court in the case of the Tobacco Trust, which applied the Sherman anti-trust law with full force to the two English companies doing business in this country, now renders it a foregone conclusion that the foreign shipping trust, both in its passenger and freight combines, will be ultimately dissolved as far as evidences of it are available on our shores, but it ought to be realised that, thereafter, such evidences must be necessarily very intangible and inconclusive "The mountains have labored and a ridiculous mouse will be born" Whatever becomes of our prosecution of the foreign shipping trust, though it be actually dissolved, which is hardly conceivable, and though by such dissolution the conditions may render possible the upbuilding of competing lines, yet those conditions alone will not produce an American merchant marine, unless and until our government shall plant the seed by new legislation, and cherish and protect the plant with favorable laws Else, the foreign grip upon our ocean shipping will remain unshaken; and to loosen it at all now will require a new birth of patriotism all over this land, sufficient to shake off this lethargy and awaken our people to a realization of their true condition of subserviency to the foreign shipping interests.

Ways and Means.

Notwithstanding the prejudice, both inspired and innocent, existing in this country against ship subsidies, it remains a fact that subsidies are the instrumentality through which existing merchant marines have been created and maintained. Subsidies and merchant marines are inseparable companions.

The constitution of the United States provides that treaties with foreign nations are a part of the supreme law of the land, and hence they cannot be set aside by a mere statute. There is now a clause in the Dingley tariff law which discriminates in favor of goods brought in American ships, but it is a dead letter, and has been set aside by the Board of General Appraisers as conflicting with our treaties. Discriminating duties must be preceded by the abrogation of about thirty treaties with foreign nations. The difficulties involved, together with the risk of retaliation, render that course well-nigh impracticable, though not impossible. Heretofore the advocacy of discriminating duties has been a means of opposition and of procrastination; with the present composition of Congress, however, it becomes not only a possibility but a live proposition. It is quite conceivable

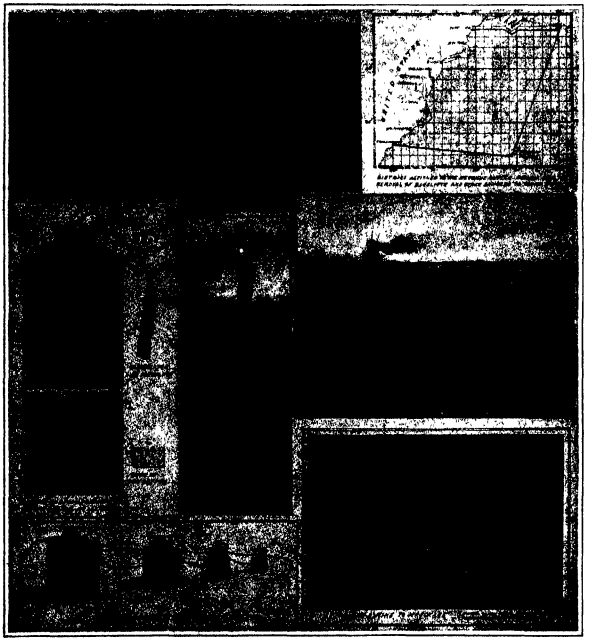
Clearing the Ocean Highway

The Derelict Destroyer "Seneca" and Her Work

By Walter Bernard

Of all the perils which beset ocean navigation, perhaps the most insidious, because the most elusive and difficult to guard against, is the derelict—the abandoned and almost submerged, but still floating wreck. When a vessel of stout construction, particularly if she be built of timber, is loaded with a cargo that is lighter than the water, she may sink until she is in the awash condition, and, by virtue of the strength of her hull, may hold together for many years, floating hither and thither at the caprice of wind and tide, and so constitute a perpetual menace to navigation. The ever-shifting wreck is naturally uncharted; and although a vigilant watch by day may suffice to detect the danger, in the night time the obstacle is quite invisible, and should it lie in the direct track of a ship a collision is unavoidable.

Unquestionably the floating derelict has been answerable for not a few of the unexplained losses of staunch and well-found ships, instances of which are too many and well known to need any recapitulation here.



The endurance of the derelict and the extent of its ocean wanderings are almost unbelievable. Take the case of the Norwegian bark "Crown," lumber-laden, which was abandoned in a supposedly sinking condition in mid-Atlantic on December 26th, 1909. In the following May it was reported as on the edge of the Sargasso Sea, and at a later date it was sighted upon the other edge of the sea, having traversed in the interval eleven hundred miles. In the summer of 1910, it was sighted between Charleston, S. C., and Bermuda.

Take, again, the case of the "Fannie E. Woolston," which was wrecked on the Jersey coast October 15th, 1891. During the following three years the wreck was frequently sighted; once off the coast of Africa, and later on the opposite side of the Atlantic, off the coast of Florida. Finally it dropped entirely out of sight.

Lloyds, of London, has developed an effective system for tracing ocean derelicts, and whenever one is sighted in any of the seven seas, it is reported to headquarters, and means are taken to intercept and destroy it.

We present illustrations of the "Seneca," a deservedly popular vessel, which was recently built for the United States Revenue Cutter Service, for the purpose of patrolling the seas contiguous to the Atlantic coast and locating and destroying both derelicts and sunken wrecks that are a menace to navigation. The patrol ground of the "Seneca" lies within a line drawn from Charleston, S. C., to just west of the Bermuda Islands; then northeast to Sable Island, and from thence westerly to the coast of Maine. Generally speaking, the vessel has no particular orders, but is free to go and come when and where her captain, George C. Carmine, may think fit. Her specific duty is to locate and destroy wrecks, and to render assistance to vessels which may be in distress whether ashore or at sea. Her home station is Tompkinsville, Staten Island, to which reports of the sighting of derelicts are brought in by shipping or by wireless, or by cable from Lloyds.

We present a series of engravings showing the methods adopted by the "Seneca" in destroying derelicts and floating wreckage. The explosive used is guncotton, which is carried in boxes, and is charged into copper canisters (mines) which measure 9½ by 9½ inches, by 12 inches in height. Each mine is loaded with 50 cubes of guncotton, each measuring 3 inches by 3 inches, by 2 inches in height, which are snugly packed within the canister, in the manner shown. In the center of the canister is a copper case containing a firing charge of dry guncotton, within which is a primer of fulminate of mercury, which is electrically detonated. Cables lead from the primer up through a threaded cap, beneath which is a rubber ball which, as the cap is screwed down, is compressed against the cables and forms a watertight joint. Rubber gaskets also serve to make a tight joint for the main cap which closes the top of the canister. A battery is used for firing. The canister as shown above is standard for all explosions, as many of them being used as is necessary to do the work.

The guncotton mines and the methods of blowing up wrecks and destroying floating debris.

CLEARING THE OCEAN HIGHWAY

To illustrate the destruction of a large sunken vessel, we show the blowing up of the wreck of the three-masted schooner "Belle Halliday," which when loaded with paving stones was sunk on Pollock Rip Slue. The hulk was lying across the tide. To destroy this wreck a series of mines (canisters) was slung on a continuous cable, which was hung between two boats. The boats were rowed into a position alongside the wreck, with the cable stretched between them. The cable was then lowered to the bottom, when it was swept by the tide in under the bilges of the ship, in a position favorable for doing its work. The firing cable was then paid out to a distance of about 800 feet and the whole charge detonated. The ship was literally torn to pieces. For the destruction of the smaller floating obstacles such as deck houses, it is generally sufficient to suspend a single canister beneath the object, in the manner shown in one of our engravings.

A frequent and dangerous obstruction is the floating mast, which generally is found bottom upward, with a portion of the mast showing above the surface and the heavier end of it, containing the heavy masthead iron fittings and gear, floating many feet below. In this case, a mine is suspended on a heavy chain ring, which is placed over the mast and allowed to slip down to its bottom. The crew row off to a distance of several hundred feet, paying out the firing cable as they go, then, by pressing the button, the mast is shivered into splinters.

It should be explained that for the destruction of the hull of a ship, as in the case of the "Belle Halliday," the mines, each of which contains 40 pounds of guncotton, are placed generally about 25 feet apart, and as a rule about eight mines form the limit in a single series. Of course, the weight of the charge varies with the size and strength of the ship. Thus, in the case of the "Anglo African," which was stranded four miles south, half east, of Cape Charles lighthouse, with her bridge deck awash and only the mainmast standing, it was necessary to employ twenty-seven of the guncotton mines to insure her complete destruction.

The blowing up of derelicts and the destruction of wreckage however, by no means represents all the duties of the "Seneca." Her work in the salvage of ships and the saving of human lives has been arduous and highly meritorious. It will be remembered that several times during the past winter she did noble work of this character.

Bacteria as Indicators of Soil Acidity

THE longer a soil is used for producing crops, the more acid it accumulates. As most cultivated plants cannot thrive in an acid soil, it becomes necessary to employ larger and larger quantities of lime for neutralizing the increasing soil acidity. It thus becomes desirable to have a convenient method for determining the acidity of agricultural soils. The chemical methods heretofore used are cumbersome and unsatisfactory.

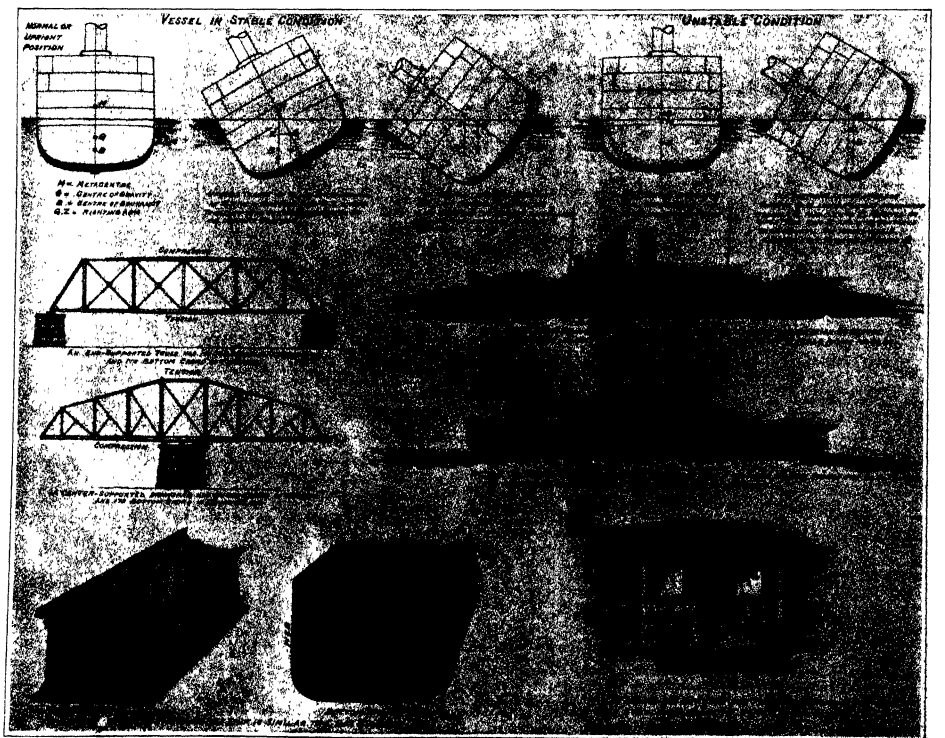
Prof. J. G. Lipman of Rutgers College has been conducting experiments with a view to finding a more expeditious and more reliable method for determining soil acidity and has obtained some interesting results by employing bacteria. His method rests upon the well known fact that bacteria will not multiply in a medium containing more than a certain percentage of acid. By comparing the growth of bacteria in a number of bouillon preparations to which varying quantities of sterilized soil have been added, it may be readily seen at what point the growth of the bacteria is stopped and accordingly the amount of acid in the soil may be calculated. In one set of experiments ammonia producing bacteria were used. A known quantity of soil is added to the bouillon, and after the action of the bacteria has proceeded a certain length of time the ammonia is distilled into standard acid and the amount determined. The amount of ammonia produced would vary inversely with the acidity of the soil, since the more acid there is in the soil the more would the activity of the bacteria be restrained. Other experiments were made with nitrifying bacteria in nitrogen-free media, the amount of nitrogen produced being used as an indication of the absence of acids.

Designing and Constructing an Ocean-going Steamer

How the Form, Size, Speed, Engine Power, etc., of an Ocean Steamer are Determined

By W. A. Dobson, Naval Architect William Cramp & Sons Ship and Engine Building Company

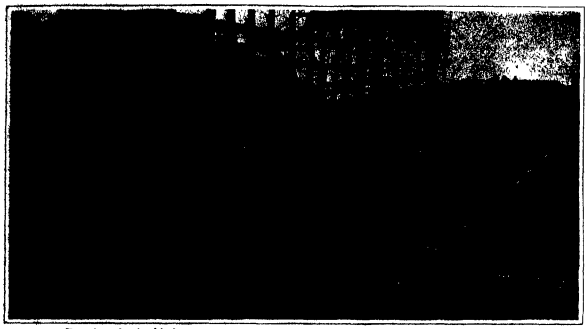
It is the intention in this article to deal with the design and construction of an ocean steamer, as nearly as may be, from the viewpoint of a layman. To tell how the successive operations of design and construction are carried on without entering into an explanation of the more or less abstruse principles involved.



The starting point is of course the requirements of the owners. Every steamship line has its own traditions, practices and customs which must be adhered to. There are, however, certain fundamental requirements which determine the size and character of the vessel. First among these is the deadweight, or, in other words, the amount in tons of cargo alone to be carried, and its general character. Next comes the number of passengers in the first and second classes and in the steerage, for whom quarters must be provided. Then the speed necessary to maintain a given schedule between the ports of entry, and the length of route covered, in order that an adequate supply of fuel may be carried. The facilities and character of the terminals must also be considered, not only from the standpoint of handling the cargo properly, but often from the fact that the depth of water obtainable must determine the very important feature of the draft of the vessel. Another feature of great importance to the welfare and comfort of the patrons of the line is to so design the vessel as to suit the climatic conditions of the route. Having this information, therefore, given us, we are ready to approximate the displacement of the vessel in the light and fully laden conditions. It is evident that the displacement of the vessel, or its weight, at a given draft must be equal to the weight of the hull with all its equipment and outfit; the machinery and all its auxiliaries; the weight of the passengers and necessary stores; plus the weight of the fuel, and the weight of the cargo carried on that draft.

It remains, then, to determine the dimensions of the vessel and the power required, in order that the weight of the hull, machinery and fuel may be accurately calculated. For reasons given above the draft is fixed, leaving two dimensions, or the length and beam, which may be varied according to the conditions to be met. For a given speed there is a length below which it is not desirable to go, it being essential to obtain the most economical expenditure of power in driving the vessel. On the other hand, if this limit of length is largely exceeded the skin friction is greatly increased. To obtain the necessary room for passenger accommodations and capacity for cargo, it often happens that this limit must be exceeded, and the resulting increase in resistance accepted. Upon the breadth, or beam, depends largely the initial stability of the vessel, or the quality of remaining upright in still water. The safety of the vessel therefore, fixes the minimum beam to which we may work.

We find, then, a limit in length and in beam below which it is extremely undesirable to go. It may very well happen, however, that these minimum dimensions will not give the necessary displacement or the fineness of form desired. It is then that the experience and skill of the naval architect must be displayed in arriving at dimensions which afford the necessary volume, seaworthy qualities and form of least resistance.

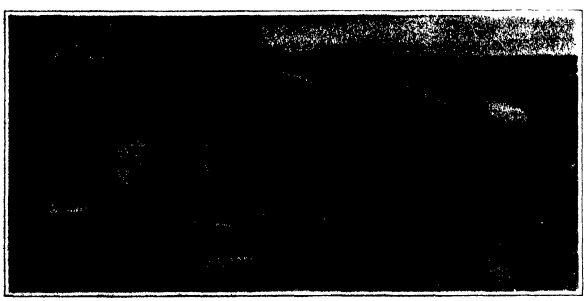


There is still another factor to be considered, and that is the depth of the vessel. The proportion of depth to beam and length affects the strength of the vessel in a marked degree. The structure for purposes of strength must be dealt with as a girder wherein the decks form the top flange and the keel, longitudinals and bottom plating the bottom flange, the side plating forming the web of the beam or girder. It can readily be seen, then, that the strength increases as the square of the depth. Under any circumstances, however, the depth must not be less than the draft plus the amount of freeboard required by the registration societies, or the freeboard necessary to comply with the Plimsoll markings. Should it be necessary to classify the vessel in one of the registration societies it may be necessary to modify the dimensions slightly to obtain a more economical arrangement of structural material, as the scantlings or the plates and shapes entering into the structure, are determined by certain rules governed by functions of length, breadth and depth.

Having settled upon the dimensions and practically upon the displacement, or within such limits as may readily be taken care of by a slight variation of the block coefficient, as the measure of the fineness of form is called, we enter upon a careful determination of the power necessary for the required speed. In all shipyards of experience extending through a score or so of years, power and speed data taken from voyages and trial trips have been carefully recorded and tabulated. These cover a great variety of forms and types of vessels. Selecting from this source the data pertaining to a ship similar in form and proportions to the vessel under design, we are able by applying Froude's law of comparisons to arrive at

The length of 600 feet for ship supported at ends is only approximate, for the stresses given.

PROBLEMS OF STABILITY AND OF THE BENDING EFFECTS OF THE WAVES



Framing the double bottom.

a very close approximation of the power required, so near, in fact, as to settle the weight of machinery and amount of fuel needed and thus finally fix the exact displacement. The plans of form, or, as commonly called, "lines," are then prepared, embodying the designer's best judgment as to the most suitable underwater form to give the least resistance. The "lines" are then sent to one of the experimental model basins, one of which is owned and controlled by the Government at Washington, and the other by the University of Michigan. Here a model is made from them, and its towing resistance at varying speeds carefully recorded and plotted. From the model resistance the effective horse-power for the actual vessel is calculated. The result of the model experiment is the final word in so far as the power required is concerned. If the result is not satisfactory to the designer he will prepare another set of lines and try them, or make such changes as a careful observation of the model under test may indicate will lessen the resistance. When finally satisfied he may rest secure from all apprehension of a trial failure caused by insufficient power.

Three more qualities of the ship as a whole remain which must be investigated, and they are the strength, trim and stability. Most vessels are built

The ship in frame and plated.

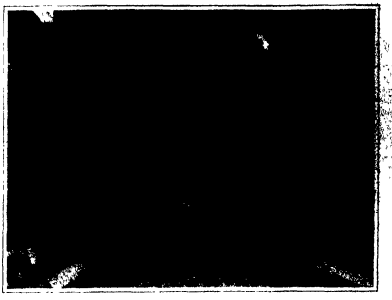
An elliptical funnel.

to be classed in some one of the registration societies, and where built according to their rules, if of the general type of construction provided for, very little apprehension need be felt regarding the strength. Occasions frequently arise, however, when a new form of construction is required to suit some particular type of vessel. It then becomes necessary to calculate the stresses coming upon the top and bottom flanges of the girder, when the vessel is either upon the crest of a wave or in the hollow, the wave chosen being of the same length as the vessel. In all conditions of the sea the vessel itself, considered as a loaded beam, remains practically the same, but the points of support are constantly changing. On the crest of a wave we have the beam supported in the middle with ends free, and in the hollow, the ends supported and the middle with little support. The estimated stress is arrived at only after complex and laborious calculations of too technical a character to be here described.

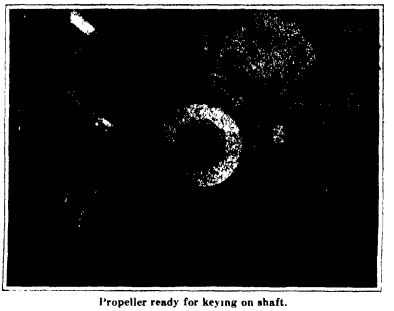
The trim of the vessel depends of course upon the relative positions of the center of gravity of the completed vessel, and the center of gravity of the immersed volume, or the part of the vessel in the water, commonly called the center of buoyancy. Both must lie in the same vertical line, and the vessel will necessarily assume such drafts as will satisfy this condition. To maintain a predetermined draft line it is necessary, therefore not only to accurately estimate the total weight but its longitudinal center of gravity as well. This must be done before the plan of form or "lines" is made, in order that the center of buoyancy may be properly located. Ordinarily, when fully laden, the vessel trims on even keel and by the stern when light.

There remains still the important feature of stability to be investigated, for upon the condition of stability depends largely the safety of the vessel. It may be said that there are three conditions of stability or equilibium in a body floating freely in still water, and these are stable, unstable and neutral. It is absolutely necessary to obtain the first of these conditions, and it depends solely upon the position of two points, one known as the transverse metacenter and the other the vertical center of gravity of the completed ship. The metacenter depends upon the geometrical shape of the underwater body, and the center of gravity upon the arrangement of the weights that enter in the *boat ensemble* of the vessel. The distance between them is known as the metacentric height. If the center of gravity is too far below the metacenter the vessel is too stiff and quick in rolling, making her extremely uncomfortable for her passengers, and if too small a distance is maintained the vessel is liable to be unstable. A reasonably small metacentric height, combined with high freeboard whereby a long range of stability is obtained, is found to give a safe, slow and deep rolling vessel, with the maximum of comfort to those on board.

There is still another condition of stability to

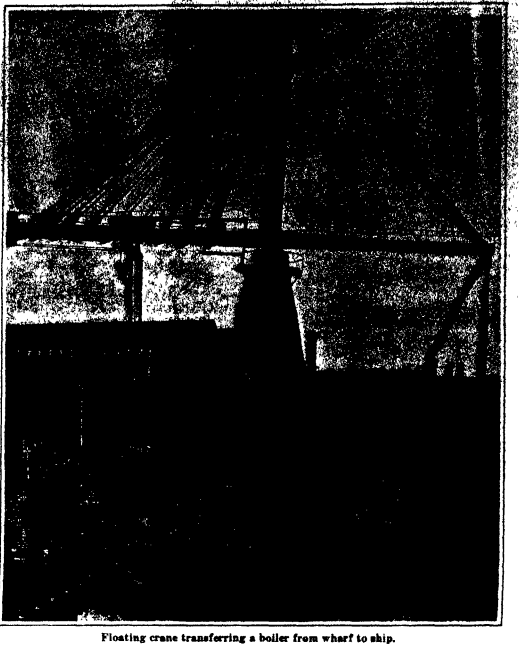


By driving in wedges the weight of the ship is transferred from the pontoons to the launching ways.



Wedging up preparatory to launching.

provide for, and that is when by accident the compartments at the ends of the vessel are flooded with water the change in trim shall not be so great as to submerge the upper watertight deck. This is provided against by the arrangement of the bulkheads at the extremities of the vessel, so as to keep the weight of water admitted and its free surface as small as practicable.



Almost all seagoing merchant vessels of the better class are fitted with Scotch boilers, arranged for heated forced draft. The motive power, however, is one that admits of careful study, the type chosen being governed largely by the wishes of the owners. For vessel over 20 knots per hour speed, the later-day tendency is, where vessels are running at

DESIGNING AND CONSTRUCTING AN OCEAN-GOING STEAMER

full speed, day in and day out, to arrange for steam turbines, although many owners stick to the old and well-tried triple expansion reciprocating engines. An excellent and most economical arrangement is a combination of reciprocating engines for the higher steam pressures, combined with a turbine for the lower.

Having settled upon the dimensions and form of vessel, the type of machinery and the accommodations for the passengers, we are ready to proceed with [illegible] material and getting the work in the yard. In this and those of all the structure of the vessel are made from which the material is manufactured, ready to be sent to the mills. Drawings of the [illegible] are prepared from which the patterns and [illegible] are made, and to which the different parts [illegible] are shaped in the shops.

The frames of the vessel are laid down full size on the floor of the mold loft from which the shape of each frame is taken. The frames come into the yard from the mills in straight pieces, which are heated and bent to the shape given by the molds. Molds or templates conforming to the shape of each frame and paper templates are made in the loft, from which the material as it arrives in the yard is laid off and planed and punched ready for erection and riveting.

The first step in the yard is to prepare the keel blocks for the reception of the keel As almost the entirely weight of the vessel up to the time of launching must rest upon these blocks, they must be of very substantial character, and should be laid upon piles with cement or timber caps so to prevent any settling of the blocks. As the vessel, when sufficiently finished, must be transferred from the building slips to the water, the blocks are laid with an inclination from the bow to the stern, to facilitate launching.

The next step is to lay the keel and the bottom plating, up to the turn of the bilge or beyond the margin plate of the inner bottom. Then the frames and the longitudinals within the double bottom are erected, and plated over with the inner bottom plating The side frames and stringers and the stem and sternpost are then erected and the bulkheads placed in position; then the beams are also placed and we are ready to put in place the side and deck plating Meanwhile the engine, boiler and shaft foundations have been built and the stern tubes and propeller struts secured in place The rudder is now ready for hanging and the vessel is so far completed as to be ready for launching.

This is one of the most interesting processes in building, for we have to transfer from the keel blocks to the water a structure weighing in some instances from twelve to fifteen thousand tons. Since the vessel as built rests upon the keel blocks and shores, it is necessary to raise the vessel up clear of them, and at the same time transfer the weight to a platform capable of being moved at will. The method generally used is to place on each side of the keel blocks a runway formed of heavy pieces of timber, made smooth on the upper surface, and framed together. The breadth is such as to support about two and a half tons per square foot of area when the weight of the vessel rests upon them. These timbers, called "ground-ways," are laid upon piled foundations parallel to the keel, and about one-third of the vessel's breadth apart. They extend from the bow down into the water sufficiently to have at least nine feet of water on their ends at high tide, and are set at a slightly greater inclination than the keel blocks When these ways are in position and properly braced and shored, their upper surfaces are coated with tallow and grease about five-eighths of an inch in thickness. Upon the greased surfaces are placed a similar set of ways free to move, when released, called "sliding-ways" These extend as far forward and aft as the form of the vessel will permit On top of the sliding ways and between them and the ship's structure a cradle is built conforming to the ship's form in the line of the ways Between the cradle and the sliding ways a multitude of long wedges are placed, which when driven up gradually raise the vessel from her building blocks, so that the weight rests upon the two greased surfaces, and is only held from moving by a heavy tie at the forward end of the ways, or a releasing trigger fitted with a hydraulic cylinder to throw it out of gear at the proper time If a timber tie is used holding the sliding into the ground ways, it is sawn asunder, and then the vessel is free to move down the greased inclined paths to the water

During the construction of the steel hull, work on the engines and boilers and joiner work has been pushed in the different shops so that the vessel as soon as launched is ready to receive her machinery and auxiliaries, and to have the passenger accommodations carried along to completion

The passenger accommodations include in their scope a small unit of almost all the plants common to a large city A water supply and drainage system must be provided; an electric plant capable of operating auxiliaries and thoroughly lighting the vessel is necessary; a ventilation system whereby fresh air is carried to all parts of the living quarters is provided; a refrigerating and cold storage plant must be provided for the preservation of fresh meats and vegetables, etc. In addition, all the conveniences fitted in a first-class hotel find their counterpart in an ocean liner There must be a laundry, with drying rooms, etc., all machinery for laundering; dish-washing machinery; a kitchen complete with ranges, boilers, steamers, broilers, warming tables, hot tables, meat-chopping and meat-slicing machines; bakery; printing office; a bar and wine room; public and private baths; barber shop, music rooms; library; lounging and smoking rooms In the first-class quarters a great field is open to the art of the decorator, who, in many instances, has produced notable examples of taste and proportion

All of these details must receive the care and attention of the builder, from the day the keel is laid until the vessel leaves his hands ready to start on an ocean voyage

Space forbids going into detail in connection with the appliances fitted and means provided to insure the safety of the passengers against fire, collision, or explosion Suffice it to say that each one of the dangers to be encountered is provided against in the most thorough and reliable manner, insomuch, in fact, that a large, up-to-date ocean steamer is about the safest place in which a person can be—though not to all people the most comfortable

Observations of a Wheat Student

To the Editor of the SCIENTIFIC AMERICAN

The writer is doing some experimenting in wheat growing that may prove of great scientific interest to the agricultural world along the lines of intensive wheat culture.

Fifty feet from my bedroom window (I am a shut-in crippled by a severe colotomy operation) I had planted a plot, 8 feet square, with six kinds of autumn wheat. The soil was good but hard-pan underlay it, giving me but 24 inches of growing earth A problem arose as to moisture sufficient to grow the wheat and sufficient plant food containing earth to nourish it I met the problems, and I see my wheat waving in the breeze, "heading" nicely and *above the 6 foot measuring rod.*

Liebig used human nitrates as a fertilizer, and increased the gluten in growing wheat from 10 to 31 per cent. A proposition of tremendous human economic interest when you think that a lean steak has but 20 per cent of animal "gluten" in it. Flour at 3 cents per pound; steak at 25 to 30 cents per pound.

I am using human nitrates in the fertilizing of this wheat. The growth is phenomenal, now it remains to be seen what the analytical chemist will find when the ripened kernels are sent to his laboratory

My theories are these: That with intensive culture (not the hit or miss trust-in-Providence methods now in use) and the proper fertilizers, our wheats can be intrinsically improved in a muscle-food building sense, and the *yields* greatly increased as well.

Lesinsky, so states the *Nova Vremyea*, grew from *one* wheat kernel planted at the apex of a funnel-shaped pit, 24 × 18 inches deep, lightly covering with earth the growing stem repeatedly until it reached the surface, 19,523 stalks of wheat, each bearing its quota of kernels! Phenomenal stooling. As the *Nova Vremyea* is a sedate Russian journal, not given over to *Punch* or *Puck* joking, one does a little thinking. Prince *Kropotkin* got, it is stated, 150 bearing stools from one kernel of wheat so growing. I am now to try out this "pit" experiment.

We are "up against it," agriculturally speaking, when our national wheat crop averages but 13 bushels as against England's intensively farmed wheat with a *yield of 32 bushels, and North Dakota's* average last year of 14½ bushels.

If my 8-foot farm yields a very high protein content in the wheat, and the fertilizing value of human nitrates can be duplicated in a commercial fertilizer, in a practical economical way, there is room ahead for scientific research as to applying better ways and means of producing our staff of life The very thought of increasing the food value in a loaf to twice or thrice its present state leans somewhat toward a reduction in the higher cost of living, for then man could, if he had to, live and live well and be perfectly nourished on "bread alone," upsetting the Biblical contention to the contrary

As my experiments progress, I may write you. I am doing what I can to exploit the soap trees of Mr Moulle of Jacksonville, Fla., in California A most useful and valuable tree seemingly

Point Loma, Cal. CHARLES CRISTADORO

Advantages of Forward Horizontal Rudders

To the Editor of the SCIENTIFIC AMERICAN

"Surface winds are well known to be oscillatory in character, i. e., subject to rapid variations of pressure, velocity and direction, altogether analogous to sound waves." (Page 422, SCIENTIFIC AMERICAN)

"The 'Canard' was practically the same machine with the body lengthened 5 meters in order to bring the horizontal rudder that much farther forward of the planes The above experimental glider, which was tested at Berck-sur-Mer when Voisin was experimenting with Capt. Ferber, was instrumental in giving the former the European record of duration as a glider" (Page 424, SCIENTIFIC AMERICAN)

Superiority of the horizontal rudder forward aeroplane being demonstrated but not analyzed in your article, I suggest the advantage of the horizontal rudder forward as a sustaining device is that it automatically lifts the front of the machine every time a gust strikes it, and has the main planes inclined upward before they are struck by the gust Similarly, it drops the front when the velocity of wind ceases. This seems a step in favor of prolonged gliding flight without engines. Practice in observing velocities and skilled adjustment of the forward horizontal rudder may bring us much nearer our dream of flight on so-called "sound waves"

I would suggest that experiments of this nature be made over the water for safety, horizontal position of aviator to reduce air resistance, and for the assistance the aviator would receive in seeing the gusts on the water before they struck his wings Assistance might be rendered from a boat with a string and reel, thus making the practice prolonged

Gliding is generally attempted on calm days for safety It should be attempted on gusty days for power Birds seem unable to glide any considerable distance on a calm day, except on conditions where an upward local current is found Such currents must be often formed on calm days on account of the sunshine warming the lower atmosphere

Denton, Md J. FRANK GELLETLEY

Dotted Guide Lines

To the Editor of the SCIENTIFIC AMERICAN:

In book catalogues and price lists, and elsewhere I have noticed the use of lines of dots, the purpose of these being to guide the eye from the thing to the number or price thereof For example

Bravo	C777-2
Afloat and Ashore	C777
Miles Wallingford	C777-15
Les Miserables	H895-3
Ivanhoe	S431-14
Redgauntlet	S431-22
Apples	40 cents
Eggs	30 cents
Potatoes	55 cents
Coffee	30 cents
Tea	65 cents

Since the lines are close together the eye is often confused and fails to pursue a straight course in passing from the thing to the number In order to assist the eye in keeping the line, and to increase the efficiency of the dots, I suggest the omission of every other line For example

Bravo	C777-2
Afloat and Ashore	C777
Miles Wallingford	C777-15
Les Miserables	H895-3
Ivanhoe	S431-14
Redgauntlet	S431-22
Apples	40 cents
Eggs	30 cents
Potatoes	55 cents
Coffee	30 cents
Tea	65 cents

When the names and numbers are far apart, and especially if the type is small and the spacing is close, it may be well to retain only every third line

Phases of Science as Other Editors See Them

Whale Meat as a Food

IN a recent number of the *National Geographic Magazine*, Mr. Roy Chapman Andrews, Assistant Curator of Mammals of the American Museum of Natural History, wishes that the European and American people could be educated to the point of eating whale meat or, as he puts it, canned flesh of animals yielding as much as 80,000 pounds of meat. This, it seems, is the point which Japan has reached: a country where thousands too poor to buy meat content themselves with whale flesh.

It was the invention of the harpoon gun in 1864 by a Norwegian Svend Foyn, that rendered this great supply of meat possible. Mr. Andrews assures us.

"With the further development of the harpoon gun grew up a new and great industry for it made possible the capture of a group of whales known as rorquals, or finners, in sufficient numbers to warrant the erection of stations at certain points on the shore where the animals could be brought in and the huge carcasses converted into commercial products. Previously these whales had been little troubled by the men who hunted in a small boat with a hand harpoon and lance, for the great speed of the animals and their tendency to sink as soon as killed, as well as their thin blubber and short, coarse baleen, made them unpopular with the early whalers.

"In a few years stations had sprung up on the coasts of Norway in every available place, and later reached across the Atlantic to the American shores. Newfoundland became the first hunting ground for the whalers here, and only a few years ago as many as eighteen stations were in operation on that island and the immediate vicinity.

"The great success of the Norwegian methods attracted so much attention that stations were erected in every part of the world where conditions were favorable—in British Columbia, Southwestern Alaska, Bermuda, South America, and the Islands of the Antarctic, on the coasts of Japan, Korea, Africa and Russia. Australia is soon to be invaded, and only a few months ago a company announced their plans for carrying on operations on a large scale in the Aleutian Islands."

In New Zealand, hump-back whale are being taken in wire nets, and so in nearly every part of the globe the world-hunt goes on. The inevitable result of this wholesale slaughter will be the commercial extinction of the large whales within a very few decades, according to Mr. Andrews.

The marvelous rapidity with which the enormous carcasses are handled and cut up is described by Mr. Andrews.

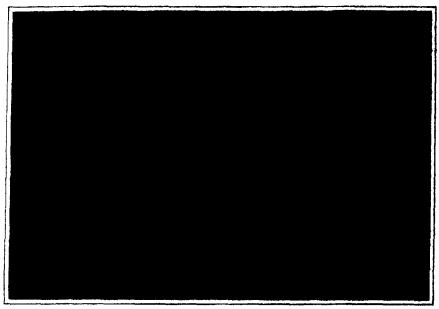
"A heavy wire cable was made fast about the posterior part of one of the whales just in front of the tail or flukes and the winch started. The cable straightened out, tightened, and became as rigid as a bar of steel. Slowly foot after foot of the wire was wound in, and the enormous carcass, weighing perhaps forty-five tons, was drawn out of the water upon the slip.

"One of the Japanese (for men of six nationalities—Chinese, Japanese, Norwegians, Newfoundlanders, Indians and Americans—are employed at these west-coast stations) scrambled up the whale's side, and balancing himself on the smooth surface by the aid of his long knife made his way forward to sever at the 'elbow' the great side fin, or flipper, 16 feet in length.

"Before the carcass was half out of the water other cutters, or 'flensers,' as they are called, had begun to make longitudinal incisions through the blubber along the breast, side and back, and from the flukes the entire length of the body to the head. The cable was then made fast to the blubber at the chin, the winch started, and the great layer of fat stripped off exactly as one would peel an orange. When the upper side had been denuded of its blubber covering, the whale was turned over by means of the 'canting winch,' and the other surface flensed in the same manner.

"The blubber is a layer of fat of varying thickness which covers the entire body of all whales, porpoises, and dolphins, and keeps the animal warm. It acts exactly as the feathers of birds or the hair of land mammals—as a non-conductor to prevent the natural heat of the body from being absorbed by the water in the one case, and the air in the other. On the great bowhead, or Greenland right whale, which lives in the intensely cold waters of the Arctic Ocean, the blubber is twelve or fourteen inches thick in some places.

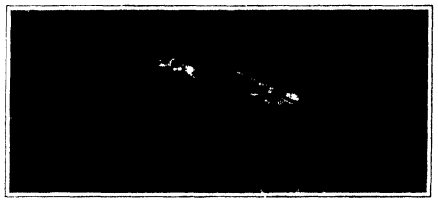
"When the 'blanket pieces,' as the blubber strips are called, were torn from the carcass, they were cut into large oblong blocks and fed into a slicing machine, clipped to small bits, carried upward and dumped into enormous vats, to be boiled or 'tried out' for oil.



"The carcass had meanwhile been split open by chopping through the ribs of the upper side, a heavy hook was attached to the tongue bones at the throat, and the entire mass of heart, lungs, liver and intestines drawn out at once. The body was then hauled to the 'carcass platform,' at right angles to the 'flensing slip,' the flesh torn from the bones, and the skeleton disarticulated.

"Both flesh and bones were piled separately into great open vats which bordered the carcass platform, and boiled to extract the oil. The flesh was then artificially dried and sifted, thus being converted into a very fine guano, and the bones pulverized to form 'bone meal,' also a fertilizer. Even the blood, of which there are several tons in a large whale, was carefully drained from the slip into troughs, boiled, dried, and made into guano. Finally, the water in which the blubber had been tried out was converted into glue.

"The baleen, or whalebone, which alone remained to be disposed of, was thrown aside, to be cleaned and dried as opportunity offered. The baleen of all the rorquals is short, coarse and stiff, and in Europe and America has but little value. In Japan, however, it is made into many useful and beautiful things."

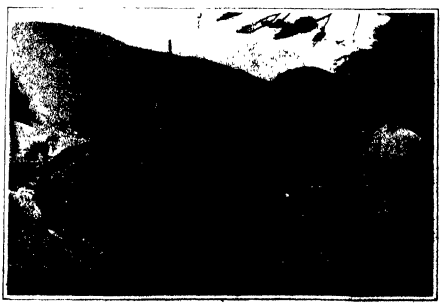


With the exception of minor details, is the method of handling whales which the Norwegians developed after years of experimenting, and which is followed in almost all other parts of the globe except Japan.

The Japanese apparently surpass all other nations in using the carcass of the whale to the utmost. Not only have they extracted the best there is in the whale and adapted them to their peculiar needs, but they have added much to their experience which whalemen of other nations would do well to recognize, Mr. Andrews believes. "Too poor to buy beef, the diet of many Japanese along the coast would include but rice, fish and vegetables, were it not for the great supply of flesh and blubber furnished by these huge water mammals. In winter the meat of the humpback whale, which is most highly esteemed, sometimes brings as much as 80 sen (15 cents) per pound; but this is unusual. Ordinarily it can be bought for 15 sen or less. But the edible portions are not only the flesh and blubber. Certain parts of the viscera are prepared for human consumption, and what remains is first tried out to extract the oil, then chopped by girls using hand knives and

The harpoon as it strikes the whale.

In addition to the rope the harpoon carries a bomb which is exploded three or four feet inside the whale and usually kills the huge animal instantly. The black cloud is the smoke from the discharge.



Towing the inflated whale to the factory.

The Bowles Bank

The carcasses of five humpback whales: Vancouver.

This whale is considerably smaller than the blue whale, its maximum size being 85 feet.

Head of the 60-foot sperm whale sent to the American Museum in New York: this head yielded 20 barrels of spermaceti.

dried in the sun for fertiliser. Whale meat is very coarse-grained and tastes something like venison, but has a flavor peculiarly its own.

"I have eaten it for many days in succession," says Mr. Andrews, "and found it not only palatable, but healthful. The Japanese prepare it in a variety of ways, but perhaps it is most frequently chopped finely, mixed with vegetables, and eaten raw, dressed with a brown sauce.

"In the summer, when it is impossible to ship the meat to any distance because of the heat, much of it is canned. The flesh is cooked in great kettles, and the cans made, packed and labeled at the stations. On my desk, as I write, is a tin of whale meat which I brought from Aikawa, where hundreds of pounds were packed and sent southward to be marketed at Tokyo and shipped to all parts of the empire."

Battle Practice in the American Navy as an Example of Efficiency

PROBABLY the most marvelous and valuable example of standardized operations anywhere in the world is on our American fleets in battle practice," so states Mr. Harrington Emerson, the efficiency engineer, in the *Engineering Magazine*. "The art of war has not changed as to its fundamentals since men first began to fight on land or sea. The purpose is with a stronger force to overwhelm a weaker opposing fleet—to strike first, hardest and quickest. It was Goliath's idea to pick off the Israelites one by one, and a modern pugilist could defeat a hundred men if they charged him singly, and he could down the first before the second came up. A 'Dreadnought' makes all the navies of the world without 'Dreadnoughts' obsolete, because such a battleship with its ten 12 inch guns can fire a broadside from all of them at once while steaming at 21 knots.

"Such a battleship steaming as fast as any rivals, bringing more guns into action than any rival, hitting an enemy at seven miles, could destroy the whole of an opposing fleet one by one, even as the pugilist would take the lighter weights one by one. But the horse-trotting, fire-fighting American stop-watch practice is also in the navy, and it was realized that if these big guns could be fired four times as fast, it would be very nearly the same as having four times as many guns or four times as many 'Dreadnoughts;' and also that if the skill of aim could be increased four-fold, if four shots would reach the target as compared to one in the older practice, one modern 'Arkansas' or 'Wyoming,' with twelve 12 inch guns, firing four times as fast and hitting four times as often, will, for the time being at least, be sixteen times as effective. These big guns are loaded, aimed, and fired twice in a minute. The practice drill is only half this time, and this practice drill is of two kinds. There is the physical act of loading the heavy gun, there is the more important act of pointing it. Two opposing ships are 10,000 yards apart (about six miles) steaming at 18 knots in diverging directions. The rate of change of range may be 750 yards a minute. If the range is set for every 50 yards, it must be redetermined every 4 seconds. This is impossible, but it can be determined every 30 seconds and a salvo be fired every 30 seconds. Being able to determine the range twice a minute, to fire twice a minute, the remaining part is drill in pointing or aiming, and this is done by means of much practice with models.

"To hit a target 60 feet wide and 30 feet high at 30,000 feet with a big gun, when you can cover it twice over by the point of a lead pencil at arm's length, is considerably harder than to hit a target 1 inch high at 83 feet with a small gun, but it is much better and much cheaper to fire 1,000 shots with the small gun than to fire the big gun once, and when the big gun is fired four times in practice, after training with small apparatus, it will do better than if firing 100 real shots without the model practice.

"In the battle practice I saw the first 12-inch range-finding shot, from a distance of 14,000 yards, go clean through a 30 by 60 target; and so accurate and secure was the aim of all the salvos that we calmly watched the shots splash all around the floating target only 400 yards away. The firing end was not less impressive. The team work was so perfect that the salvos from the same ship were redirected one after the other almost with the ease with which a child swings a garden hose.

"I have also watched diminutive and juvenile Igorot savages shoot dimes from a forked stick at 60 feet with bow and arrow. The Igorots show us the beginnings of offensive skill; modern American battleship target practice shows us the highest speed, accuracy, and distance yet attained, and we may not doubt that our present achievement is but a step in man's ultimate achievement.

"The improvement in the effectiveness of the different ships of the navy in the last five years is very great, and is probably the greatest improvement both in importance and magnitude that has ever been accomplished. Think of the small degree to which the steam turbine is superior to the reciprocating engine (a questionable 5 per cent), or how very little faster the best passenger trains are than the slowest of the same class (about 25 per cent). Think of the enormous expense in time and money spent in developing either steam turbines or high-speed trains, then think of the sixteen-fold increased efficiency of our battleships as compared to five years ago, an increased efficiency due to the application of the principles of efficiency—*all of them*—Ideals, Common Sense, Competent Counsel, Discipline, the Fair Deal, Reliable and Immediate Records, Schedules (of 10,000 yards), Dispatching (of big shot at the rate of ten or twelve a minute), Standardized Conditions, Standardized Operation (secured by constant and assiduous team drill), most minute Standard-Practice Instructions (as to how fifths of seconds can be saved in time), finally, a joyful and much coveted Efficiency Reward, in both honor and emolument, when the tremendous results have been accomplished. And when this appears not only in the spectacular gunnery, but also in the more prosaic but continuously important operations of firing coal; of coaling ship (the record as to this having increased from 30 tons an hour to 360 tons an hour on some of the ships for the whole cruise around the world), of the maintenance of operation of machinery on board ship without going to navy yards—these accomplishments show that high efficiency requires neither great outlay nor protracted time but only the proper intelligence, spirit and organization. The sea going form of organization is admirably adapted to apply the principles, since a gun drill, a coal drill, a recoaling drill, is but a practical and modern form of drill. The ideal is not a mere dress parade, but to hit accurately, fast, and furiously, at the greatest distance, an enemy's ship overtaken by better management throughout; and this ideal has been accomplished stop watch in hand, refining all the conditions and operations, this refinement made possible by bringing to bear all the available knowledge in the universe. This navy work is a great game not drudgery. It is pleasurable excitement and joyously hard work."

Good Roads and the Motor Truck

THE experience already accumulated with the motor vehicle has abundantly demonstrated that one necessary feature to its successful use is good roads. There are few existing types of motor vehicles capable of carrying large loads which can compete as yet with the 10 or 20 mule team on the Western plains. That there are possibilities in this direction will certainly be admitted, and some manufacturers are already working in this direction, witness the "Caterpillar" traction engine recently illustrated in these columns and the farm tractor.

In the opinion of the *Engineering News*, it must be said that the motor vehicle is at present confined to good roads. "When it strikes a soft spot or a slippery spot, it has an uncomfortable habit of digging a hole and burying itself with a promptness that would make any ground-burrowing animal known to zoology ashamed of its feeble efforts.

"An excellent exemplification of the dependence of motor trucks upon good roads is furnished by the experience of an enterprising truck manufacturer who last fall sent a 5-ton truck to make a journey from Denver to Los Angeles, loaded with 3½ tons of lumber.

"It took 68 days to make the journey of 1,519 miles from Denver to Los Angeles, an average distance of about 22 miles per day.

"The journey was made," the *Engineering News* presumes, "to demonstrate the ability of the truck to pass unscathed over the roughest and most unpromising territory. What the demonstration really showed, however, was that if the truck or any other vehicle of similar construction is to be operated at a profit, it must have reasonably decent roads to run on. Judging by the official accounts of the trip which were given out, the load of lumber was pretty well worn out during the journey through its frequent use ahead of the truck to carry it across soft spots in the road.

"Such freight hauling by motor vehicle may be good advertising but it is not good business. In fact it is extremely doubtful whether any vehicle weighing as much as four or five tons with its load can be profitably run over soft dirt roads.

"The advent of the commercial motor vehicle is interesting to highway engineers from two points of view. In the first place it will enormously increase the demand for good road construction. In the second place it will likewise enormously increase the wear and tear upon road surfaces. Perhaps this is the most important engineering problem of all those presented by the advent of the motor vehicle.

"As every engineer engaged in highway construction knows, the advent of the pleasure automobile has revolutionized our whole problem of highway construction, has practically doubled the cost per mile of permanent macadam roads and has probably much more than doubled the annual cost of maintenance. It has been hoped by the engineers who have most to do with road problems that a fairly satisfactory solution has been reached through the use of the latest and best forms of bituminous macadam involving an increased expense in construction and maintenance about as outlined above.

"If, however, as seems not only probable but certain, we are in the near future to add to our present heavy passenger automobile traffic the traffic of heavy motor trucks, carrying loads of two to eight tons and propelled at speeds reaching 20 miles an hour or higher, what sort of road surface can the engineer provide that will stand the wear, and yet not exceed the taxpayers' limit of elasticity? We shall not attempt to answer this question. We doubt whether any one is wise enough to answer it now; but it is one that will have to be answered in the near future.

"Sooner or later, the heavily burdened taxpayer is certain to raise a protest at the enormous burden imposed upon him for road maintenance. Sooner or later, conservative sentiment will awaken to the foolishness and wickedness of unloading upon posterity the burden of paying for good roads which are destined to be worn out long before posterity arrives. Sooner or later, we must place upon the owner of the automobile the burden of paying for the wear and tear which his machine produces upon the roads.

"The fool propaganda of good road enthusiasts has widely disseminated the notion that good roads are cheap to build and once built cost little to maintain; and this notion has caused a vast amount of trouble for engineers.

"It is important that the public should understand that *good roads cost money and a lot of money* to build and to maintain, and that with the advent of the commercial automobile *their cost per mile* for both construction and maintenance is likely to be materially greater in the future."

The Adventitious Arsenic in Fruit

THE use of Paris green as an insecticide on fruit trees has been pretty generally abandoned because of its solubility and the consequent injury to fruit and foliage. The substitution of arsenate of lead has been on the whole more satisfactory, although, as P. J. O'Gara points out in *Science*, a careful examination has shown that this substance is not altogether without objectionable features. In the preparation of arsenate of lead by the combination of either the *nitrate* or *acetate* of lead with *disodium* arsenate, there are formed three distinct lead arsenates in varying proportions. The ortho-arsenate, $Pb_3(AsO_4)_2$, is practically insoluble in neutral or alkaline water, and so quite harmless. But the *meta*-arsenate, ($PbHAsO_4$), is commonly very injurious; and the *pyro*-arsenate, $Pb_2As_2O_7$, may become so when the water used contains in solution chlorides, sulfates or carbonates—which means practically all common waters.

In addition to burning or spotting of leaves and fruit, varying quantities of the arsenic are absorbed. Chemical analyses showed this amount to vary with the degree of spotting. In some spotted apples the skin showed, in a 10-gramme sample, as much as 0.05 milligramme of arsenic, in a single apple there was a total of 0.3 milligramme.

The presence of arsenic in the paper used for wrapping the fruit for shipping is also a source of danger. The writer refers to one shipment of pears from the Pacific coast in which all the fruit came from one orchard and was treated exactly alike, two different kinds of paper being used. When taken from storage one half was much farther advanced in ripening than the other, and the difference corresponded to the presence of arsenic in the paper. That arsenic hastens the ripening process has been known for some time.

The writer warns fruit growers about the quantity and the composition of the arsenate of lead used in spraying, and about the brand of paper used in wrapping the fruit.

Bent by the Sun

THE towering Washington monument, solid as it is, cannot resist the heat of the sun poured on its southern side on a midsummer's day, without a slight bending of the gigantic shaft which is rendered perceptible by means of a copper wire 174 feet long, hanging in the center of the structure, and carrying a plummet suspended in a vessel of water. At noon in summer the apex of the monument 550 feet above the ground, is shifted, by expansion of the stone, a few hundredths of an inch toward the north. High winds cause perceptible motions of the plummet, and in still weather delicate vibrations of the crust of the earth, otherwise unperceived, are registered by it.

Development of Ore-handling Machinery

THE development of ore-handling machinery in connection with ore transportation on the Great Lakes is a good mechanical illustration of the doctrine of the survival of the fittest. The millions of tons of ore accumulating in the

George W. Hulett, who has introduced a number of important innovations in machinery for handling materials.

Lake Superior region have to be transported to their lake destination during a period of not to exceed eight months in each year. Here, if anywhere, time has been the "essence of the contract." One type of apparatus has replaced another almost as soon as its mechanical and time-saving advantages have become apparent.

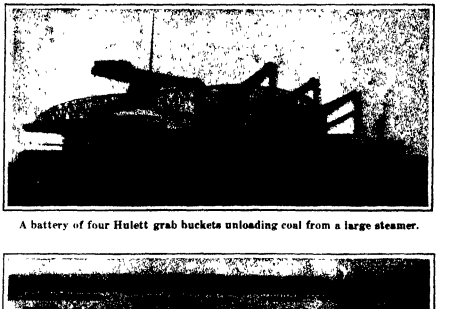
Every development in ore-handling machinery has been based on two ideas, namely, that of increasing the speed with which the ore is handled, and that of reducing the cost. The work divides itself naturally into two distinct operations, the loading and the unloading. The problem of loading the ore into the boats has been a simple one—gravity suggests an obvious solution, and some form of elevated bin and chute is everywhere used. Unloading, however, has always been a more difficult proposition, and has furnished a fertile field for the exercise of the inventive faculty. It is the object of this article to touch briefly upon a few of the types of devices which have been used from time to time for this purpose, and to conclude with a short description of the two leading types of machines now in use.

Originally the ore was shoveled into a bucket or tub, which was hoisted and swung around by an ordinary crane. The bucket was dumped into a traveling lorry or car located on an elevated track, and when the car was filled, it was taken to the stock pile and dumped. In a few years the single crane and bucket gave way to a battery or set of cranes all operated by a common hoisting machine. Crude and uneconomical as this apparatus is, it is still in use to a limited extent.

About 1880 Alexander E. Brown of Cleveland, O., and others, brought forth the first examples of the now well-known "unloading bridges." The prime advantage of the unloading bridge, in its early form, was that by it ore could be distributed over a large area. It also dispensed with the lorries or cars used in the previous construction.

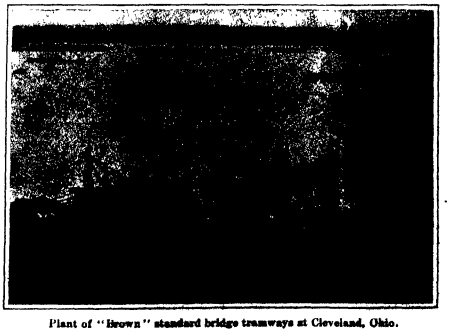
The first unloading bridge consisted, essentially, of two towers or piers traveling on tracks laid parallel with the docks, a cableway joining the towers; an apron or boom pivoted to the front tower and projecting over the water, and a bucket-supporting carriage or trolley traveling on the cableway. The bucket was hoisted and its travel controlled by means of a cable or cables which led to a hoisting machine located in the rear tower.

Within a few years the cableways were generally replaced by rigid trussed trackways. These trackways usually extend beyond the rear tower to afford a larger travel of the bucket. However, the cableways are still used to a limited extent in places where the installation is to be used for a short time only.



It is desirable to so arrange the bridge that it may be slewed through an angle of fifteen or twenty degrees with respect to the track. Special pivots, allowing for both vertical and horizontal swinging motion, are therefore provided between the trackway and each of the supporting towers, and the bridge is propelled along the tracks by separate independently operable motors, so that either tower may be moved without moving the other.

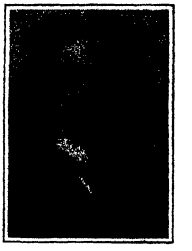
It is also desirable that the apron or boom may be movable to and from working position without interfering with the rigging of the boat. This has been accomplished principally in two ways. First, by means of a telescopic track-end which may be projected or retracted horizontally, and, second, by providing the boom with rollers at its inner end, which rollers travel up and down a vertical trackway on the front tower, the outer end at the same time being supported by guys. This arrangement causes the outer end of the boom to be projected and retracted along a line that is nearly horizontal.



In the bridges recently constructed, the hoisting drums are mounted on the traveling carriage or trolley. This carriage also supports an operator's cab from which point all motions of the unloading bridge are controlled by a master controller. The special advantages of so mounting the drums and cab are that it avoids the use of long traversing cables, and places the operator in a position from which he can see and accurately direct all movements of the bucket.

The usual length of the unloading bridge is from 180 feet to 250 feet, but bridges are in use in which the track length exceeds 500 feet. Those at the Indiana Steel Company's plant at Gary, Ind., are 495 feet long, and the towers are spaced 187 feet from center to center. The usual height of the track above the yard is about 60 feet. The power used to operate the Gary bridges is as follows. To open and close the bucket, four 80 horse-power motors, to traverse the trolley, four 40 horse-power motors; and to move the bridge, four 30 horse-power motors.

The type of device by which the bucket has been hoisted and transported is one invention, the particular form of bucket, another, and they have not developed hand in hand. During the life of the crane-and bucket unloader and for several years after the advent of the unloading bridge, the buckets in use comprised the combination of three elements. The bucket body, the supporting bail, which was pivoted to the bucket body at a point below its center of gravity when filled, and a latch connecting the bail and bucket body. When the latch was released the bucket was reversed and dumped by the weight of the load. The great disadvantage of this type of bucket is that it is not self-filling at least not when used with ore. Probably the most arduous and man-killing work connected with the ore-handling industry is the shoveling of the ore into the buckets. It is slow, dangerous and costly. This condition led to the invention and development of the grab or clam-shell bucket, which may be said to have been one of the most important steps in the whole ore-unloading art.



A battery of four Hulett grab buckets unloading coal from a large steamer.

Plant of "Brown" standard bridge tramways at Cleveland, Ohio.

This bucket, in its simplest form, comprises, as is generally known, two co-operating halves or jaws pivoted together, and a means for opening and closing them. The means employed may be a drum and two chains or cables, in which instance the drum is mounted on the

A. E. Brown, the originator of the "unloading bridge."

pivot, or on a frame supporting the pivot, with a chain or cable connected to each of the bucket-halves. In another type toggle levers are substituted for the drum and chains. The bucket is usually supported by two cables. When suspended by one of the cables the jaws are held open by the weight of the bucket itself; when supported by the other cable they are automatically closed. In the operation of the grab bucket it is held open and allowed to drop jaws-down, which causes it to become partially imbedded in the ore. The other cable is next hauled in, the result being that the jaws are closed. The bucket is afterward hoisted. Upon reaching the dumping point, it is again suspended by the opening cable, and the material is discharged.

The capacity of the clam-shell used in unloading bridges varies from 5 to 15 tons. Ordinarily it does not exceed 7½ tons. It is said that bridges equipped with 5-ton buckets will unload on an average about 200 or 250 tons per hour. The buckets are designed to make from 60 to 70 trips per hour, and consequently, it is not unusual to handle 350 tons per hour during the first part of the unloading of a ship.

The cost of operating these bridges, considering also interest and depreciation of plant, is said to be about five cents per ton of ore unloaded.

The clam-shell unloader, however, has this disadvantage, namely, there is no weight, other than that of the bucket itself, to force it into the material. The bucket also swings to an undesirable extent. To overcome these defects, a later type of unloading machine—that invented by Mr. George W. Hulett of Cleveland, O. was designed.

This machine comprises the following elements: A gantry bridge traveling on tracks laid parallel with the dock; a carriage traveling to and from the dock-front on girders which connect the legs of the gantry bridge; a pivoted walking beam supported by the carriage; a vertically extending leg pivoted to the end of the walking beam; a link or equalizer pivoted to the carriage and to the leg and co-operating with the walking beam to cause a parallel motion of the leg; and a grab bucket connected rigidly to the lower end of the leg. The leg may be

rotated by a cable and bull-wheel to extend the bucket in any direction.

In operating this machine the whole device is propelled along the track until it is opposite the hatch from which ore is to be taken; the carriage is run out on the gantry bridge until it is over the ore, after which the bucket-leg is lowered, it being brought positively to loading position by the combined action of the walking beam and the connecting link; the bucket is then closed about the ore, the motion of the walking beam reversed, the carriage backed, and the bucket dumped.

The "Brown" grab-bucket.

Since the moving parts are very heavy —the whole machine weighing about 460 tons where a bucket having a capacity of 10 tons is used—it is essential that the movement be reduced to the lowest possible limit. For this purpose and in order to save time, the gantry bridge is provided with a second pair of tracks, upon which a traveling hopper is supported. These tracks are extended as a cantilever at the rear of the bridge. The bridge itself straddles four ordinary railroad tracks. Consequently the hopper may be dumped into a car on any one of these tracks or run out on the cantilever extension and there discharged into a stock pile.

The control of the various motions involved is an important consideration. One operator rides in the bucket-leg close to the bucket, and has control of the hoisting, lowering and rotation of the leg, and the opening and closing movements of the bucket. Another operator directs the movement of the carriage, of the hopper, and also of the machine along the dock. The controllers, proper, for all these motions, are located near the respective motors, and are in turn controlled by small drum controllers located at the operator's stations.

The following data are given concerning the power used by the Hulett unloaders at Gary, Ind.: To open and close the bucket, 80 horse-power; for operating the walking beam, 150 horse-power; for moving the carriage, 50 horse-power; and for operating the hopper and propelling the whole machine along the track, 75 horse-power; total, 355 horse-power.

When equipped with 10-ton buckets (the usual size), each machine frequently unloads 500 tons per hour, making the capacity of each unit about 500,000 tons per season, working days only. Four steam-operated machines at Conneaut, O., have averaged 403 tons per hour on a 7,000-ton boat, and the maximum taken out by a single machine in an hour was 631 tons.

Don'ts for Air-brake Inventors*

DON'T forget that successful invention is not a pastime nor a subliminal uprush, but an evolution from long experience, painstaking observation, careful analysis, intimate familiarity with the varying requirements and local conditions in all parts of the country, thorough knowledge of mechanics and the laws of nature (not the least important of which are embodied in the M C B rules of interchange and the rulings of the Interstate Commerce Commission), a severe disregard of non-essentials and of repeated failures and an unfailing persistence, born of optimism, the courage of proven conviction, and hard, common sense.

Don't confuse invention and financiering. To invent is not synonymous with "to get rich quick."

Don't assume a parental attitude toward an invention. Fatherly sensitiveness and solicitude only add a sting to failure, while real merit will need only the backing of cold, hard facts to substantiate its claims.

Don't be satisfied with yourself or your first or even last idea of a device. Look for the defects, not the merits in any design you propose to patent. The latter will always take care of themselves. An apparent success, however, is oftentimes more fatal than flat failure. The latter at least tells the truth and usually teaches a valuable lesson, the former raises false hopes and obscures the truth and results in a corresponding greater failure when the final reckoning does come.

Don't forget that there are always two sides to every question, especially in the case of a mechanical device. None are so bad as not to have some good points. On the other hand, the merits of a device may be many and important, and yet its patent value worthless on account of non-interchangeability, too great refinement, previous patents covering the same idea, and so on.

Don't expect to get something for nothing. Whenever such appears to be possible it will surely develop that the net gain is worth exactly the price paid, namely, nothing. Stored energy can be made to perform useful work only by a transformation from a higher to a lower level, by a progression from the concentrated to the diffused, never in the reverse order. The process of converting the energy in a pound of coal into available form as live steam is on a descending scale, never at 100 per cent efficiency nor anywhere near it. Again the conversion of the energy of steam into available drawbar pull at the tender is attended by still further losses. These examples are but typical of every process by which mechanical work is performed. No mechanical system can be operated at 100 per cent efficiency; at best it only approximates this figure under the most favorable conditions of the laboratory.

Don't mistake "possibility" for "practicability." Many things are possible, but only a few are practicable.

Don't think because a really practicable device can be designed to perform some function, that it deserves to be universally adopted. To deserve attention this function must be distinctly useful and more, it must be definitely and unqualifiedly on the side of increased safety or economy of operation.

Don't attempt to find a remedy for a known defect by getting around the effect, but first discover the cause and overcome that.

Don't mistake the troubles which come from careless and improper handling or laxity in inspection and maintenance for inherent defects in the apparatus, these troubles require betterment in instruction or maintenance, rather than improvement in design.

Don't expect to find road and laboratory conditions the same. They are not.

Don't be surprised if a device which works perfectly (?) on a test rack proves unmanageable in a service test. Dirt, abuse, misuse, neglect, water, frost, heat, over-lubrication—all are in favor of such a difference.

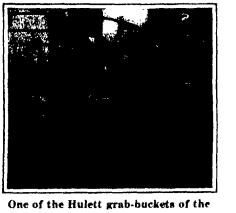
Don't overlook existing apparatus and conditions.

Don't forget that in the air-brake any failure in function of any part must be in the direction of safety—not of danger. In other words, a failure must cause the brakes to apply—not to release or prevent a brake application when one is attempted.

Don't think because a device will operate satisfactorily in itself that it will meet with instant and unqualified success. For example, the electro-pneumatic brake is an ideal system for long train service, and was so acknowledged in the official report of the M C B Burlington brake trials ("The best type of brake for long freight trains is one operated by air and in which the valves are actuated by electricity.") But it is not and probably will not for some time be adopted in steam-road freight service on account of fundamental mechanical, practical and economic considerations, the force of which is patent to anyone familiar with what such a change would involve.

Don't forget that the millions of dollars of capital already invested in existing equipment prohibit the introduction of any device which will not work in perfect harmony with the apparatus now in use under every conceivable condition of service.

Don't allow mechanical ingenuity to obscure the limitations imposed by the laws of pneumatics and mechanics or considerations of practicability and economy.



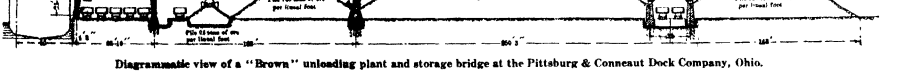
Don't think that an air-brake device stands alone. Not only is it affected by surrounding conditions and other devices with which it is associated, but it in turn also affects to a greater or less degree all other members of the system in which it operates.

Don't place too great faith in the results obtained with a single device or under a single fixed set of conditions. Railroad conditions demand that air-brake appliances work as well on a 50 or 100 car train as on a single car and under the most unfavorable as well as favorable conditions. Many devices and systems will work marvelously well alone or in short trains or under favorable laboratory conditions and yet be totally unfit for long-train or mixed service or subject to fatal disarrangement or entire failure when exposed to neglect, extremes of weather or careless handling.

Don't neglect friction. Usually there is more friction than can be conveniently provided for at every point in the brake apparatus, except where it is most needed, viz., between the brake shoe and wheel. Here there is seldom enough.

Don't assume that air can move instantly. Air has inertia and requires time to change from a state of rest to motion.

Don't consider air as being without friction. The friction between a moving column of air and the walls of the pipe



One of the Hulett grab-buckets of the battery shown unloading a steamer.

or passageway in which it moves may be considerable, and productive of unexpected and disconcerting results when not properly allowed for. For example, it has already been shown that with the triple valves cut out the brake pipe may be left wide open at the front end of a 100-car train and instead of an instantaneous drop in pressure throughout the length of the pipe the last quarter of the train remains at its original pressure, without perceptible drop, for fully twelve seconds. This is the result of the combined effect of inertia and friction.

Don't spend time, money, or energy upon devices which depend for their proper operation upon different rates of rise of brake-pipe pressure. Much of the first 25 or 30 cars the difference between a high or low excess pressure or the use of release or running positions of the brake valve handle can barely be detected by the most delicate recording apparatus.

Don't overlook the variability of the human equation. As long as there is any possibility of mishandling or wrong manipulation, it will surely be found, for there are a thousand ways in which a thing may be wrong, done and but one right way. It is for this reason that "fool proofness" takes high rank among the prime essentials of all air-brake devices.

Don't overlook the fact that simplicity, interchangeability, fool proofness and low first and maintenance cost often have more to do with the success of a device

Diagrammatic view of a "Brown" unloading plant and storage bridge at the Pittsburg & Conneaut Dock Company, Ohio.

than ingenuity of design or merits of construction.

Don't fail to consider the economic features of any device which is to be proposed for patent. Safety and protective features being equal a net gain in dollars and cents must be shown over and above the rating of the apparatus to be displaced or added to before any excuse can be offered for even considering a change.

Don't consider the ordinary materials of manufacture indestructible. The results of wear must be foreseen and provided for if the apparatus is to be practicable.

Don't expect to accomplish results by

* Abstracted from the Third Annual Report of the Block Signal and Train Control Board to the Interstate Commerce Commission.

means of large supply reservoirs located at different points in the train to be connected into the brake pipe to assist in releasing and recharging The danger characteristic of all such schemes, viz, an undesired release of the brakes or in ability to apply them when an application is all mpted is inseparable from any system in which the derangement or failure of the mechanism controlling the connection between the brake pipe and stored volume permits the brake-pipe pressure to be increased when not intended

Don't forget that cars must be handled in yards and terminals without the brakes being coupled up and without air in the brake systems

Don't lose sight of the fundamental functions of the brake system as a whole No device, regardless of how perfect its individual design, construction or operation may be, can be tolerated which carries with it the possibility of interference with the normal operation of the brake as a whole

Don't attempt to eliminate what appears to be a defect without considering carefully what effect the means adopted will have on other functions of the brake as a whole While the desired improvement may be possible it may be at the expense of trouble in other directions of such greater moment as to prohibit the change proposed

Don't try to cure apparent defects of design or function by the use of additional devices subject to the same or worse objectionable features The cure is bound to be worse than the disease Usually it can be overcome in a better manner than by the use of additional devices

Don't expect the proposal of a novel brake system for steam road service involving the use of two brake pipes to be received with favor by the railroads If American railroad practice would permit of the use of an extra brake pipe, with hose connections between cars, some one of the hundreds of schemes of this sort patented from time to time would no doubt have been adopted long ago The fact that on y one brake pipe is tolerated in modern American practice, when considered along with the self-evident and sound reasons why this is the case, should be sufficient to effectually discourage further efforts in this direction The differences between steam and electric or European service conditions are a sufficient explanation why two, or even more, air pipes have been successfully used in the latter case

Don't forget that mechanical locking devices intended to hold the brakes applied while descending grades depend for their proper action upon such close adjustment and sensitiveness of operation and involve such a multiplication of parts that the fundamental requirement of a brake device, viz, absolute reliability is lacking at the outset

Don't permit any device to become associated with the brake pipe in such a way that its failure to act as intended can, by any possible chance, prevent an application of the brakes or cause a loss of the brakes if applied

Don't fail to recognize the brake pipe as the one and only central nerve of the air brake system and to treat it accordingly It is not to be furnished with attachments except under stress of positive necessity and only then after provision has been made so that any failure on any part to perform its function will be on the side of safety and not danger Put yourself in the place of the submarine diver some fathoms be ow the surface of the sea and consider what your views would be upon a proposal to ingraft various accesso devices along the air tube whose integrity spells life to you at that moment Much the same feeling animates those responsible for the insurance of traffic stability and the safety of human lives with regard to the preservation of the functions of the brake pipe.

Don't mistake convenience for necessity Where the necessities already tax the capacity of the system as a whole to the utmost, as is the case with the air-brake, mere convenience without demonstrable economy, either in maintenance or service operation, is not to be considered

Don't expect to provide a satisfactory safeguard against rare contingencies by means of apparatus requiring careful adjustment, frequent cleaning, and so on, to insure its being always in proper working order The usual resu t in such cases is that the protective device becomes inoperative through neglect due to fancied security and fails to work at the critical moment

Don't think that because an idea is new to you it is new to the air-brake art Most of the simple and practicable methods of accomplishing desirable results have been covered by patents for many years The odds against a simple and practicable device such as railroads want and are willing to accept, being new are therefore great As any working device is usually made up of a combination of a number of simple princip es it follows that before even taking out a patent, surely before becoming enthusiastic over the va ue of an idea, cold-blooded skepticism will save many dollars and much disappointment later on The very small cost of a search for previous patents related to the same idea will save valuable time and money, and in most cases convince the embryo inventor that he is far from being the first in the fie'd That this advice is not mere personal opinion or a desire to quench ambition's spark, but is the simple, unvarnished, but in the end merciful truth of the matter, will be acknowledged by all who have made a study of the art It is, moreover, precisely the basis upon which all manufacturing organizations conduct their development of new apparatus Nothing is left for chance or taken for granted All that has been done in their line is classified and studied minute y Thousands of dollars are spent in sifting out the old from the really new and patentable If this is sound business policy for the large concern, with unlimited resources, how much more wise and prudent for the individual of limited means, who can not afford to spend time and money without reasonable assurance of profit

In a word inventing is an art of the highest type, requiring peculiar genius, training and experience, while the capacity for appreciating or foreseeing the real value of a patent is an entirely different thing, requiring quite a different sort of skil l and education Consequently even the best inventors are rarely, if ever, capable of accurately gaging the value of their own inventions from a purely patent standpoint

Protecting an Undeveloped Patent

AN inventor is frequently confronted with the problem of protecting an invention which he has conceived, pending his perfection and completion of the improvement and at times he misses the apparent protection of a public record which at one time he was able to secure by the filing of a caveat. When an inventor conceives an invention, which is not the idea that some such improvement might be made in some way or other, for conception of an invention includes a thought of the means by which the invention may be carried out in practical form when he so conceives of an invention, he should proceed with a l the diligence at his command to complete the invention into form for practical use and should use it successfully in the presence of reliable witnesses who can be depended on to testify not only truthfully, but accurately as well to the successful operation and construction of the device Pending the completion of his invention, the inventor should preserve all sketches, drawings, models and descriptions, made from time to time, with the dates of making and with the signatures of reliable witnesses, with the dates of signing and shou'd preserve all records, bills for materials and the like, so that they may be available for evidence should a contest ever occur, bearing in mind that the better his preparation for a contest, the less likely he is to experience one.

Notes for Inventors

Artificial Rain.—A method of producing artificial rain for farmers has been invented by Mr Emilio Olsson, of Buenos Ayres, and has been copied in France and Germany Mr Olsson is now in this country for the purpose of introducing his invention His system has been used with great success on an experimental farm near Buenos Ayres One of the Olsson installations is in successful use at the Peluffo Gardens in the Calle Rivadavia, and consists of three lengths of one-inch piping, two lengths being placed at an altitude of five meters, and the third at a height of 3½ meters, in accordance with the height of the plants watered Each length of piping is fitted with two jets of four spouts each, the effect produced is exactly that of a shower of rain Mr Olsson has devised a method whereby the water can be charged electrically, with the result that not only are crops greatly improved, but that insect pests are destroyed

A New Indicator for Ships.—An English newspaper account tells of a newly invented "direction and rotation indicator" for steamships which is to be placed in the chart room and bridge and enables the navigator to see at a glance the speed and direction of the engines and number or revolutions per minute When ordering "ahead" or "astern" at any speed the indicator instantly tells whether the order is being executed

Tales of an Assistant Examiner.—A prominent New York attorney tells of an experience with an assistant examiner of the Patent Office, with whom, in an interview, he found it difficult to come to any definite conclusion about anything involved in the discussion Finally, almost in despair, the attorney said "Now," addressing the examiner by his title, "will you agree with me that this claim is either allowable or is not allowable?" and after due consideration the official gave this guarded reply "That the claim is allowable or is not allowable Well, for the sake of argument, I will agree that the claim is allowable or is not allowable" If all the stories that have been told of this assistant examiner, who is as generous and bighearted as he is peculiar, were gathered in a volume, the result would be some interesting and amusing reading

Reciprocity in the Patent Office.—Reciprocity, or retaliation if you please, is found in the Patent Office rules, in the provision that any foreign patent attorney, not a resident of the United States, may be registered as entitled to represent as attorney applicants before the Patent Office if the country of which said patent attorney is a citizen grants the same reciprocal rights to citizens of the United States, and no foreign patent attorney will be recognized in any application filed after June 30th, 1908, unless his country grants reciprocal rights to our attorneys As a matter of fact, it is thought that only three foreign nations, namely, Canada, Mexico and New Zealand, extend the privilege to patent attorneys of the United States, so that the number of foreign attorneys entitled to registration here is very limited

The Frequency of Automobile Fires.—Is there not needed a fire extinguisher especially adapted to extinguish fires accompanied by the burning of gasoline or resultant gases? The extinguisher should be adapted to be carried on the machine, where it can be detached and brought into play by a by-stander even if the machine has turned turtle, and the extinguisher should be so distinctive in structure or appearance or both, as to be quickly identified and selected from the other equipment of the machine. Should the appalling loss of life from this cause continue, it would not be surprising to find the public urging the enactment of laws requiring as a life saving means, that machines be supplied with suitable or standard extinguishers as a pre-requisite to the issuance of the license to the operator

A Long-delayed Patent.—Geo. Francis Myers, of Columbus, Ohio, is the patentee, No 995,550, of a flying machine which has the appearance of the lower half of a sphere. It is made with a number of circular aeroplanes arranged one above the other and gradually increasing in size toward the top and a car is provided at the bottom and has a propeller for moving the machine laterally. The application on which this patent issued was filed in 1904 and is a continuation of an application filed January 29th, 1897, over fourteen years ago. We wonder what will be gained by the delay, and so will all who know something of the aerodynamics.

Pumping Snow.—Snow disposal is now considered a big problem and Cadwallader Evans, Jr., of Pittsburg, has patented, No. 995,446, a method of removing snow from city streets by which he gathers the snow in quantities, then he agitates the co'lected snow at the same time adding water, the mixture is then heated, bringing it to a condition in which it can be handled by pumps and he then pumps it to some suitable disposal point.

The Inventor and the Milliner.—To provide for quickly producing hats of different styles is the purpose of a patent, No 995,990, to David Stern of New York, who provides a brim and crown and then fits a supplemental crown around the brim crown This mounting of a separate crown around the main crown enables the use of different supplemental crowns to secure the desired effect and the two crowns can be trimmed separately which is a great convenience to the milliners

A New Way of Operating a Vacuum Cleaner.—Operating a vacuum cleaner by the force of water discharged from an ordinary water service spigot is contemplated in a patent, No 995,969, to Beecher W Junk of Toledo, Ohio, who provides a main pipe to couple to the spigot and an air pipe leading to the main pipe, the ordinary vacuum cleaning tool being connected to the air pipe. He has a spiral sleeve in the water pipe which causes the water to have a whirling motion and produces an air suction up through the air pipe or hose He thus produces a device which can be attached to a water spigot and cause the water to produce a vacuum.

Take Up Your Bed and Climb.—An article of furniture useful as a bed by night and a ladder by day is the subject of patent No 995,430 to Jerome Arsenault and Chas Larrivee of St. Flavie, Quebec, Canada. They make a bed whose side rails and end rails have bars and rungs between them so the bars when the bedstead is taken down, can be handily used as ladders.

Distilling by Induced Electric Currents.—A patent, No 994,022, has been issued to the assignor of Robert J. McNitt of Niagara Falls, N. Y., for a process of distilling substances which cannot be distilled by the application of external heat on account of the destructive effect of such heat upon the wal's of the distilling vessels, the process consisting in generating the required degree of heat by induced electric currents. The process appears to be especially designed for distilling alkali metals from their alloys.

Milling Grain in a New Way.—Harry M Blinn of Baltimore, Maryland, has secured a patent, No. 995,819, for a milling process in which grain is pulverised in its entirety to reduce it to an impalpa-

LEGAL NOTICES

OVER 66 YEARS' EXPERIENCE

PATENTS

TRADE MARKS
DESIGNS
COPYRIGHTS &c.

INVENTORS are invited to communicate with Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D. C., in regard to securing valid patent protection for their inventions, Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured.

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our Hand-Book on Patents will be sent free on request.

Ours is the Oldest agency for securing patents; it was established over SIXTY-five years ago.

MUNN & CO., 361 Broadway, New York
Branch Office, 625 F St., Washington, D. C.

PATENTS SECURED OR FEE RETURNED
Free report as to Patentability; Illustrated Guide Book, and What To Invent with List of Inventions Wanted and Prizes offered for inventions sent free. VICTOR J. EVANS & CO., Washington, D. C.

Classified Advertisements

Advertising in this column is 1. cents a line. No less than four nor more than 12 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

DEAFNESS.

THE DEAF HEAR INSTANTLY with the Acoustigon. For personal use, also for churches and theatres. Special instruments. You must hear before you purchase. Booklet free. General Acoustic Co., 23 Beaufort St., Jamaica, N. Y. City. Paris branch, 8 Rue d Hanovre.

HELP WANTED.

WANTED—GENERAL SUPERINTENDENT to take charge of a sheet metal stove shop employing 100 men. Must be thoroughly familiar with sheet metal work, factory management and equipment. He must be strictly sober, efficient and have good constructive ability, and be able to furnish first class references as to character, experience and ability. Only those who can fully qualify need apply. Address supt. Box 773, New York, N. Y.

FOR SALE.

MOTORCYCLES CHEAP—Send to day for free catalog of new and used motorcycles. Also motorcycle accessories and attachable outfits for converting bicycles into motorcycles. Shaw Manufacturing Company, Dept. 38, Galesburg, Kans.

PATENTS FOR SALE.

EXCELLENT OPPORTUNITIES are offered the purchaser of the U. S. or Canadian patent rights on Self Flushing Water Pulser, introduced by medical and mechanical experts. For further particulars address H. Brenner, 401 East 105th Street, Cleveland, Ohio.

MISCELLANEOUS.

FREE—"INVESTING FOR PROFIT" Magazine. Send me your name and I will mail you this magazine absolutely free. Learn how to invest a dollar anywhere—get this magazine. It is worth $10 a copy to any man who has $100 or more or can save $10 per month. Tells you how $1.00 can grow to $10,000—how to judge differences between investments that Real Earning Power of your money. This magazine six months free if you write at once. H. L. Barber Publisher, 450, 32 W. Jackson Blvd., Chicago.

THE MOST POWERFUL FLASHLIGHT in the world. Heil groland, Germany. Post cards of this and many other lighthouses home and foreign sent us. We are specialists in lighthouse postals. Catalog free anywhere, or send 25 cents in stamps of any nation and we will send 12 assorted cards, also catalog. Lighthouse Mission, Dept. 7 S. A., 79 Lr Abbey St., Dublin, Ireland.

CIVIL SERVICE EXAMINATIONS open the way to good Government positions. I can coach you by mail at small cost. Full particulars free to any American citizen of eighteen or over. Write to-day for Booklet 34 B. Earl Hopkins, Washington, D. C.

LISTS OF MANUFACTURERS.

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

INQUIRY COLUMN

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & Co., Inc.

Inquiry No. 9340.—Wanted, addresses of owners of limestone land running not less than 95 per cent, and near a railway.

Inquiry No. 9341.—Wanted, addresses of owners of properties suitable for tree preservation.

Inquiry No. 9342.—Wanted, addresses of makers of [illegible].

Inquiry No. 9343.—Wanted, address of maker of [illegible] for [illegible].

Inquiry No. 9344.—Wanted, address of manufacturer [illegible] rubbers, cushions, and rubber for [illegible] tires.

Inquiry No. 9345.—Wanted, addresses of parties having raw materials or minerals containing potash in [illegible].

Inquiry No. 9347.—Wanted, to buy a Parcelex [illegible].

Inquiry No. 9348.—Wanted, the name and address of manufacturers of road rebuilt and pan holders, such as are used [illegible].

Inquiry No. 9349.—Wanted, by a patent solicitor, a [illegible] which could be operated on a [illegible] and which could be reversed.

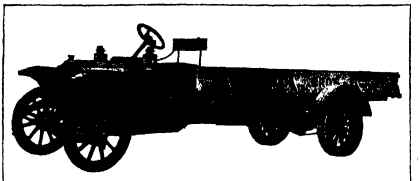
Inquiry No. 9350.—Wanted, the name and address of parties who can supply [illegible] for [illegible].

bie powder and branny flakes are coated with the powder thus formed, the product being a flour middlings in which is incorporated a portion of impalpable cereal powder which coats the bran in the middlings.

Driving a Moving Picture Film Frictionally.—A patent, No. 994,042, has been issued to the American Moving Picture Machine Company of New York for a film actuating mechanism including means for driving a film by frictional contact with the edges thereof, the mechanism employed including a rotatable member which is arranged frictionally to engage with the edge of the film.

Wanted: A Rivet-heating Machine.—There is considerable inventive activity along the line of pneumatic riveting machines universally used in the erection of structural steel work. There does not appear however, to be any attempt to displace the picturesque blacksmith with his portable forge high aloft, who, with unerring aim, tosses the red hot rivets into the nail keg held by the riveter, but he will pass also when some enterprising inventor devises some means of heating the rivets at the very place where they are applied (electrical heating, possibly), and it is not too much to believe that they may be brought to a riveting heat in a suitable heater and fed one by one directly to the holes formed to receive them.

A New Vacuum-cleaner.—A patent, No. 993,343, has recently been issued to P. D. Brewster of East Orange, New Jersey, for a vacuum dust collector having a pipe to carry the air and dust and a water tank, together with means for introducing water from the tank into the dust pipe together with means for producing the vacuum and separate means for drawing the water and mud from the dust pipe and delivering it into the water tank.



An Extensible Round-top Table.—Charles W. Munz of Detroit, Michigan, has secured a patent, No. 993,539, for a round-top table which can be extended. The table includes in connection with the permanent top a circumferential series of leaves for enlarging the said top in the same plane and supporting means for the extension leaves.

New Railway Truck Side Frames.—A series of patents, numbered 993,575 to 993,578, inclusive, have been issued to Edson C. Covert of New Kensington, Pa., for truck side frames for cars including, in most of the patents, the journal box in its connection with the members of the side frame, such journal box being integrally secured in some instances and removably weld-secured in another instance.

Crape and the Inventor.—A device for holding crape to a door is covered in the patent, No. 995,472, to Frank and Lambert of New York as assignees of Harry T. Loomis, also of New York. The holder is made with a back bar to be attached to the door. This back bar has forwardly projecting teeth to bite into the crape and a spiral spring is connected at one end of the back bar and extends over the crape to press it against the teeth of the back bar and hooks at its other end to the back bar.

Another Patent Dedicated to the Public.—Mr. Alonzo D. Melvin of the Bureau of Animal Industry at Washington has just obtained a patent, No. 986,025, which he has formally dedicated to the public. The patent is for a stamp for marking meat. The stamp has a rubber head carrying the inscription and provided with a flexible rubber shank made in one piece with the head and held in a socket in the end of a handle.

Why Not an Earth Tamping Machine?—Recently in passing a number of laborers ramming down the earth in a ditch which was being filled, it occurred to the writer why some machine had not been produced which could be managed by one man and operated to ram in the earth

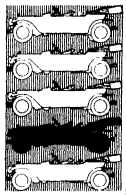
Possibilities of Motor-Trucks Unlimited

THERE is practically no limit to the possibilities of motor-trucks in the business world. Every man who has a cartage problem is anxious to know just how motor-trucks will work out under his conditions. But the question is solved—The White Company have hundreds of trucks in operation in almost every conceivable kind of business—under practically every known condition—and there is not a single owner to whom we could not refer a prospective buyer. Not one has been disappointed, but on the contrary each has found that the White truck has exceeded his expectations.

Increased Service White trucks serve their owners, first of all, by increasing the service. They make it possible to do things you have never done before—to secure trade you were unable to reach—to be prompt where you were compelled to be dilatory before—to increase your service and thereby increase your business.

Increased Economy Under the majority of conditions, White trucks increase the economy of your delivery—not always—there are conditions where trucks only increase the service. The truck replaces two or three teams—is not as expensive to maintain as two teams and requires no more men to operate than one team, saving salaries.

White Trucks—The Solution



White trucks solve your delivery problem, by increasing your service or increasing the economy of your service, or both, because they are well designed for economy's sake, having the long-stroke, medium-bore engine, which is powerful but economical. They are built for economy's sake because we use the best materials modern science has produced—the special alloys of steel, heat-treated, that are best suited to the various purposes to which they are put. White trucks are made in three sizes, with engine standardized in all types, to simplify the mechanical problem, and make White trucks adaptable to any business, any special or unusual requirements.

Let us submit a solution of your delivery problem, with catalogue and testimonials of the world's largest users.

The White Company

838 East 79th Street, Cleveland

One car in five

ONE car in five goes out of commission every year. Why?

More cars have been spoiled by improper lubrication than by any other one cause.

Properly lubricated, many of these cars would be giving satisfactory service to-day.

If you expect the car you use this season to give proper service next season, you can't afford to neglect lubrication.

Our experience in the manufacture of oils for many specific purposes has enabled us to produce in Polarine a lubricant of the highest efficiency for gas engines.

Polarine is the result of extended processes of refining, pressing and filtering.

We have practically eliminated the carbon-forming elements. At the same time, we have preserved the proper lubricating qualities.

Before the final product leaves the plant it must test up to the most rigid standards ever set for a gas engine lubricant.

Polarine

Polarine retains proper "body" at high temperatures.

It flows freely at zero.

It does not break up or lose elasticity under severe friction.

The Polarine Brand covers:

POLARINE OIL (in gallon and half gallon sealed cans, in barrels and half barrels), POLARINE TRANSMISSION LUBRICANTS, POLARINE CUP GREASE and POLARINE FIBRE GREASE.

These lubricants cover the needs of every part of the car.

Send to our nearest agency for "Polarine Pointers" which includes hints on the care of motor cars.

Standard Oil Company
(Incorporated)

just as it was being done by the gang of laborers Now that gasoline motors are so adaptable, the machine could be kept ready for instant use, could be supplied with rammers limited in number only by the size of the framework and the capacity of the engine, and the engine could be utilized to move the machine from place to place as well as to operate the rammers Of course, many problems would have to be solved, but they would doubtless yield to the skill of an ingenious inventor

General Otis and the Patent Office.—General Harrison Gray Otis, who has gained increased notoriety through the blowing up of his newspaper plant in Los Angeles, and his controversy with organized labor, was at one time an official of the Patent Office at Washington, where he was chief of the corps of proof readers prior to the organization of the Issue and Gazette Division. General Otis was appointed to the Patent Office from Marietta, O., in May, 1871, and resigned January 31st, 1876, thus serving in the Patent Office a little less than five years

An Implement for Cleaning Ceilings.—The cleaning and scrubbing of ceilings is frequently a difficult matter and an implement has been patented, No 994,204, by T A Schoenlau of St Louis, especially designed for the purpose It has a funnel shape body to put up against the ceiling in which are provided rotating brushes to which a cleansing fluid is delivered to cleanse the ceiling

A New Continuous Current Arc Lamp.—Inventions in arc lamps are nearly always interesting and along this line Max Korting of Leutzch, near Leipzig, Germany, assignor, in a patent, No 994,261, presents a continuous current arc lamp which has a number of depositing surfaces supplied with electric potential, one of the surfaces being connected with one terminal of the lamp and one with the other terminal

A Mechanical Sparring Partner.—Exercising devices are quite popular and a patent, No 992,862, was issued last year for such a device in the form of a dummy or figure representing a person of normal size and mounted upon a freely rocking weighted base permitting it to swing in all directions. The body portion of the figure is suitably stuffed or inflated and the person exercising may strike it with his bare fists or may use gloves and the figure, when struck, will be caused to rock rapidly on its weighted base simulating the action of a punching bag The weighting of the base causes the quick return of the figure after it has been struck and as the figure may move freely over the floor when struck, the user secures considerable practice in foot work as well as in striking. This sparring partner suggests the possibility of a wrestling partner and no reason is seen why a wrestling partner should not be invented which could in many ways operate to exercise the person desiring practice on the mat

Wanted: An Automatic Grain-shocker.—In an article by W. J Brandon, in the *American Thresherman*, the statement is made that in the grain fields there is an opening for an automatic grain-shocker, which can be sold at a reasonable price Such a machine would be another great aid to increased efficiency "No machine," he states, "has yet been put upon the market that shocks the grain successfully"

The Ozone Generator.—In the SCIENTIFIC AMERICAN of May 27th attention was called to the suggested necessity of an ozone generator in commercial form, adapted for what might be termed popular use Since then, the attention of the writer has been called to the so-called ozonator made by the General Electric Company and fully described in the *General Electric Review* of June, 1911, in an article which includes the physical and chemical properties of ozone and a description and illustration of the device. This is said to be the practical result of years of experimentation. The device includes means for providing ozone when the current is applied a blower for forcing air through the ozone chamber and diffusing the ozone throughout the room, suitable connections insuring the running of the blower at all times when ozone is being produced Connections for the current and for the switches for controlling the same are provided and the apparatus presents a neat, compact and business-like appearance

Theory vs. Practice in Invention.—B was the inventor of a new machine for stoning peaches and M was a successful inventor who had made good inventions and had been able to market the same in a way to make a pronounced commercial success B's peach stoner was a marked departure from anything that had gone before and he was proud of the practical evidence of his originality. Appreciating M's experience along the patent line, B asked him his opinion of his new invention After careful examination M said: "Your machine is all wrong in principle, but," he added, "I made a machine for taking the stones out of peaches that was all right in principle My machine which was all right in principle would not work in practice Possibly your machine which is all wrong in principle will work all right in practice" I never learned whether B's machine was a practical success.

Wanted: A Humane Dog-muzzle.—The dog muzzling time is now at hand No one questions the discomfort, if not the cruelty, of many of the muzzles now in use Have you ever thought of the tremendous market that is ready and waiting for some one who can devise a simple, inexpensive, efficient and essentially humane muzzle? Such a muzzle would be welcomed by the dog owners and, since it could be worn without annoying the animals, would avoid the dangers resulting from the removal of the muzzle, especially after nightfall, when the guardians of the law are not so likely to observe conditions

Legal Notes

Establishment of Trade-mark Rights.—What is sufficient initial use of a trade-mark to establish trade-mark rights is frequently questioned The Court of Appeals of the District of Columbia in the recent case, decided April 3rd, 1911, of Bratenbach and F H Strong Company vs Rosenberg, says

"Every trade-mark must have a beginning, and it would be unreasonable and unjust to say that it must be general, and the article widely known before the trade-mark in the name affixed to it, and indicating its origin, can be acquired"

In this case, the Court of Appeals quoted with approval an opinion of the Circuit Court of Appeals of the Seventh Circuit in Malzkaffee Fabriken vs. Kneipp Med. Co., 82 Fed Rep., 321, as follows:

"It is enough, we think, if the article with the adopted brand upon it, is actually a vendible article in the market, with the intent of the proprietor to continue its production and sale It is not essential that its use has been long continued, or that the article should be widely known, or should have attained great reputation The wrong done by piracy of the trade-mark, is the same in such case as in that of an article of high and general reputation and of long continued use. The difference is but one of degree and in the quantum of injury A proprietor is entitled to protection from the time of commencing the use of the trade-mark."

The Ownership of a Trade-mark Not Originated by the Owner.—In the case of Nestle & Anglo-Swiss Condensed Milk Co vs. Walter Baker & Co., Limited, the Court of Appeals of the District of Columbia on April 7th, 1911, reversed the decision of the Commissioner of Patents and held that where the opposer was not the originator of the trade-mark consisting of a waitress in Quaker or Puritan costume carrying a tray, such opposer has no right to exclude every one else from using the representation of a woman as a trade-mark upon goods similar to that manufactured by it.

A Thoroughly Sound Timber Bond

Netting 6%

These bonds are secured by First Mortgage upon standing timber, land, mills, railroad and other property conservatively valued at nearly four times the amount of the issue. The stockholders have an actual investment behind the bonds of more than two and a half times the bond issue. Based upon present operations the net earnings will show a large margin over principal and interest requirements. The mortgage provides for a sinking fund sufficient to retire this bond issue from the exhaustion of considerably less than half of the timber security. The bonds mature in equal semi-annual installments from six months to ten years and the margin of security will rapidly increase. We recommend these bonds as a most conservative investment.

SHARP Rotary Ash Receiving System

So Simple a Child Can Operate It

Does away with unsightly ash barrels and inconvenient ashes and drudgery of ash disposal. No rolling of ashes on the entire floor—no furnace dust in your throat rooms. Elementary conditions surrounding all rooms must be maintained in removable, sifting, iron cans with the ashes in a common-lined vault. All odors and dust go up the chimney. Mechanically perfect—a practical solution of the ash and garbage problems, satisfactorily guaranteed.

Easy to Move Ashes to Portable Cans

The Sharp Rotary Ash Receiving System can be installed in new and under any style of House Heating Furnace or Boiler, before or after it is in operation. Ashes fall directly into strong iron cans that revolve readily on Ball-Bearings, and the can is easily removed. Write today for illustrated booklet, giving full particulars, Estimates and Catalogue No. 24 sent free on request.

Holds 2 to 12 weeks ashes, removal of which is so often required.

THE SHARP CO.

RECENTLY PATENTED INVENTIONS.

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Pertaining to Apparel.

FLEXIBLE CONNECTION.—J. H. O'BRIEN, Illion, N. Y. An object of this invention is to provide a device in which a plurality of members are movable relatively to each other against the tension of a spring, the members having attached thereto flexible connections, for supporting in various manners, with a yielding tension due to the resilience of the spring.

Electrical Devices.

TELESCOPIC MAST FOR WIRELESS TELEGRAPHY, SIGNALS, AND SIMILAR USES.—A. F. JUILLAC, 25 Rue de Meaux, Paris, France. In extending the folded mast the sleeve is brought into position to allow pawls to engage the uppermost tube ferrules. The crank shaft moves the sleeve upward on the standard and elevates the said tube, which when at its highest point, the top of a second tube is clamped on its bottom by means of a rod. The sleeve is then lowered and engaged with the second tube, and when again moved upwardly, both tubes are lifted. When the second tube has reached its highest, the top of a third tube is clamped on the bottom of the second and the sleeve lowered and engaged with the bottom of the third tube. This is repeated until the mast is extended. Means provide for folding the mast.

Of Interest to Farmers.

MANURE LOADER.—A. S. STORM, Clear Lake, S. D. This invention provides a device which forms a platform or carrier for the material to be handled as the same is moved in the first instance, provides a runway or inclined rear bed to move the carrier above the body of the vehicle by which it is to be moved, provides a mechanism for moving the carrier by the incline to dump the same, and provides a mechanism simple and operable by means of the power device convenient to farms and localities where an apparatus of this kind is employed most generally.

VARIABLE CHANGE GEAR FOR PLANTERS.—A. M. CRISMAN, Davenport, Iowa. The invention is an improvement in variable chain gear for planters use, and the object is to provide a device of the character specified whereby the movement of the seed dropping plates of a planter may be varied so that different amounts of seed may be planted in a hill without stopping the planter.

AUTOMATIC PLANTER AND CHECK-ROWER.—A. M. CRISMAN, Davenport, Iowa. The present invention is an improvement over a prior patent granted to Mr. Crisman, and its object is to provide an automatic dropping device for depositing a predetermined number of grains in hills at equal horizontal distances from one another, regardless of inequalities of the ground, and wherein a minimum of work is imposed on the measuring wheel, the actual operation of dropping being done by the carrying wheels.

Of General Interest.

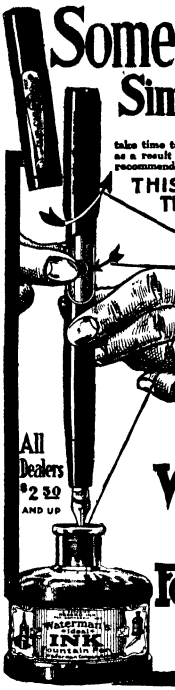
LOADER FOR CONCRETE BATCH MIXERS.—W. H. TUTTLE, Moodville, Ind. This mixer is arranged to permit accurate measuring of the quantities of materials at the time they are filled into the loader, to allow convenient charging of the loader and delivering the materials to the drum of the mixer, at the same time supplying the water in a measured quantity, thus insuring the formation of batches of concrete of uniform consistency.

METHOD OF PREPARING SCREENS FOR COLOR PHOTOGRAPHY.—L. D. DU HAURON and R. DE BERZHOUL, Tonkin-le-Haut, Tonkin, France. It is sought in this invention to cover a transparent or translucent surface of glass, celluloid, paper and the like, with a very large number of exceedingly small rectangular figures, such as bands, rectangles, lozenge-shaped figures, etc., having three distinct colors placed closely together without leaving any interval, and each covering theoretically one-third of the surface. The process is rapid and economical.

DIE.—M. F. BUEMS, Leipsig, Germany. The invention relates to dies more particularly for use in stamping letters or other characters into printing metal. The aim is to provide a die so formed that the characters impressed into the metal thereby have no deleterious effect on the metal surrounding them, so that when impressing a character no lateral swelling or bulging of the metal takes place.

TOOTH FOR EXCAVATING BUCKETS.—E. L. PEMBERTON, New Haven, Conn. The object here is to provide a tooth having a detachable point, so secured to the body of the tooth that it may be reversed when desired. In practice the points usually become worn on the lower cutting surface, and it is the purpose to provide a tooth with a reversible point so that great additional wear may be obtained.

AUXILIARY DRAINING TUBE.—P. S. PLACE, Alfred, N. Y. The tube is for use in convenient insertion in a vein or artery of a human body to be embalmed, and it is arranged to permit its insertion to any depth to insure proper draining of the blood from the vein



Some Pen Users Simply Cannot

take time to refill the regular style fountain pen—as a result Waterman's Ideal Self-Filler is strongly recommended.

"HERE ARE THE FIVE COLUMN SELECTOR KEYS"

The 1912 Everitt

An Extraordinary Automobile Announcement

The 1912 Self Starting Everitt "Six-36" Price, Fully Equipped, $1850

Six And Four-Cylinder Self-Starting Cars Of The Very Highest Character—All Chrome-Nickel Steel Construction—Big Wheels and Tires—Demountable Rims—Completely Equipped, With Top, Windshield And Speedometer—Prices $1850 and $1500 Respectively, And The Splendid "Everitt 30" For $1250

At last anyone can buy a strictly first-class Six Cylinder car, *of the very highest character*, for less than $4000.

I think what this announcement means! A magnificent "Six," comparable only with the finest of its type, built throughtout as are only a few of the very best —of costly Chrome-Nickel Steel; Self-Starting—no cranking, with big 36 x 4-inch Wheels and Tires and Demountable Rims; Long Wheel Base of 126½-inches; fully Equipped, with Top, Windshield and Speedometer, containing everything you could ask of the best $4000 car—and all at a price of $1850.

And, like all the new EVERITTS, it is manufactured complete in one factory by the latest automatic machinery, its design and manufacture is supervised by three experts of a national reputation, its inspection is probably the most severe given an automobile, and its performance—as judged by everyone who has tried it—is *wonderful*—simply *wonderful!*

The New Everitt "Four-36" For $1500

But, extraordinary as this "Six," the 1912 EVERITT line offers still another new model equally as remarkable

This is the new "Four," rated at 36 Horse-Power, but actually almost unlimited in power, speed and ability. Like the "Six," it is built throughout of the incomparable Chrome-Nickel Steel; it has the unfailing EVERITT Compressed-Air Self-Starter, operating by a push button on the dash, it has big 34x4-inch Wheels and Tires and Demountable Rims; a 115-inch Wheel Base, genuine Honey-Comb Radiator of the Cellular Type, a Double Drop Frame; Dual Ignition, and is completely equipped with Top, Windshield and Speedometer, all at the price of $1500

EVERITT

This new "Four," like the EVERITT "Six-48," is a car you can compare, in appearance, ability and excellence of manufacture, and without the slightest reservation or apology, with what you consider the very finest cars of its type, regardless of cost

The Standard "Everitt 30" For $1250

During 1911 the standard "EVERITT 30" won for itself universal recognition as "the best $1500 car on the market." It was admittedly the greatest value offered in any medium-priced automobile.

Its manufacture will be continued and the car will further improved for 1912 but by reason of many factory economies it is possible to offer this splendid car at a new price of $1250. And this includes Complete Equipment, with Top and Windshield

The new models are ready. Our Advance Catalog tells the whole story. Send for it today

Metzger Motor Car Company, Detroit, Michigan

YOU WILL HAVE A BOAT THIS SUMMER

So should every healthy, red blooded man or boy. ¶ Then build it yourself by the Brooks system. ¶ Add a little of your money to a little of your spare time and profitably enjoy many a dull hour. You can own just the boat you are looking for, at a ridiculously low cost.

MAKE $1.00 DO THE WORK OF $3.00

How? By purchasing the full-sized paper patterns and instructions for a boat, or by purchasing all or part of the material in the block—down that is every piece cut to shape, machined and accurately fitted, so that it will go together but one way, the right way. ¶ Send to-day for catalog No. 25. It tells the whole story and shows an extensive line of boats from canoes to cabin cruisers

Brooks Mfg. Co., 1705 East Ave., Saginaw, Mich.

or artery, and to allow convenient cleaning of the tube while the same is in use, with a view to keep the passage open for the blood to readily flow out.

GROUND ANCHOR.—J. SCHAUMBURG, Oschersleben, Germany. The purpose in this invention is to provide an anchor for removable connection with the ground and adapted to secure in place ropes, chains and the like, and the improvement is more particularly adapted to secure balloon or airship sheds, and devices pertaining thereto

Hardware and Tools.

OIL CAN RACK.—T. MILLER, Springboro, Ohio. In the present patent the invention consists in constructing a metal skeleton rack, shaped to secure an oil can of usual construction, and a spring pressure member to bear against the side of the can to hold the same firmly against holding members on the rack.

RAZOR.—H. J. MILLER, New Orleans, La. In this instance the invention has reference to razors, and has for an object the provision of a foldable razor having a blade removable from the shank of the razor, so that a new blade can be employed to replace the worn blade, and a guard to permit of cutting the beard or the like without marring the skin.

ATTACHMENT FOR LADDERS.—E. C. MEAD, Elkhart, Ind. In this invention use is made of notched retaining bars secured to the body of the ladder, railings mounted to swing on the bars, means on the bars and adapted to be disposed in the notches of the bars for adjustably supporting the railings and the last being provided with means for supporting packages or receptacles thereon

PIPE WRENCH.—L. P. FITZGERALD, Coalinga, Cal. This wrench is for use in handling pipes, oil well casings and the like, and more particularly to a device of this class comprising a handle, a head secured thereto and having a gripping jaw, a flexible member having one end movably secured to the handle, and means whereby the other end of the flexible member can be adjustably and removably secured to the handle

Heating and Lighting.

ATTACHMENT FOR GAS FIXTURES.—J. H. CATO, Kansas City, Mo. This attachment is adjustable to gas fixtures, and offers a suitable support for a number of brackets carrying smoke bells at their outer ends. An object of the invention is to provide an article which is capable of adjustment on the gas fixture, so that the smoke bells may be suspended in any desired position.

Household Utilities.

KNOCKDOWN COUCH.—I. E. EMERSON, Baltimore, Md. The invention provides portions of the adjacent chair structure which may be removed from normal position to be fitted between the adjacent chairs locking the same in fixed position and forming, in conjunction with the seats thereof, a bed mattress, and provides chairs with complementary auxiliary sections which may be removed from the normal position to form, in conjunction with other chairs and like complementary sections thereof, a reclining structure

Machines and Mechanical Devices.

SHEARING MACHINE.—J. F. LEAKS, Knoxville, Tenn. This invention is an improvement in shearing machines, and the object of the inventor is the provision of a simple and easily operated machine of the character specified, wherein the upper turret is moved angularly simultaneously with the lower turret, and is moved vertically with the ram toward and from the lower turret.

HORSE FEEDING MACHINE.—JOHN B. JONES, Fairmont, W. Va. The invention provides a machine wherein grain may be measured in bulk quantity to agree with weight, provides a machine wherefrom various quantities may be delivered, the regulator for said quantities being operated by means of selecting devices, and provides a simple and effective measuring device controlled by a simple construction to provide a variety of effects

FEEDING ATTACHMENT FOR TYPE WRITING MACHINES.—H. M. BUSCH, Atlanta, Ga. The invention relates to improvements in feeding attachments for machines for feeding envelopes, telegraph blanks, etc. An object is to provide a device by which an envelope or blank which is crimped, whose surface, therefore, is not in a single plane, may be fed through the device and with as much certainty as envelopes or blanks which are not crimped, and which, therefore, present a plane flat surface to the feeding member.

Designs.

DESIGN FOR A GLASS VESSEL.—C. F. FRANCH, Honesdale, Pa. The design in this case is representative of a wine glass or goblet, along very graceful and simple lines, the ornamentation comprising a band encircling the article near the rim, the band being decorated with a flower repeated and separated by interwining laces

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full links to correspondents are printed from time to time and will be mailed on request.

(12480) W. D. says: Astronomers state that the North Pole of the earth is inclined toward the sun 23½ degrees at the summer solstice, and the South Pole 23½ degrees at the winter solstice. They accompany this statement with a drawing purporting to show the inclination. The only proof given in support of this claim that the poles have such inclination in text-books on astronomy which I have seen is the change of the seasons. It seems clear that the change of the seasons could be accounted for on the theory that the earth's axis is parallel to the axis of the sun and that the plane of the earth's orbit intersects the plane of the sun's equator at an angle of 23½ degrees. If these conditions existed, the rays of the sun would reach 23½ degrees over the North Pole at the summer solstice and 23½ degrees over the South Pole at the winter solstice. Has it ever been mathematically demonstrated that the poles of the earth are inclined toward the sun as stated and illustrated in text-books on astronomy? Or is any proof given except the change of seasons? A. We are not able to agree with your statement that "the North Pole of the earth is inclined toward the sun 23 degrees 30 minutes," etc., since the pole is a point, and a point cannot be said to have an inclination to a line. We should say that the earth's axis is inclined to the plane of its orbit at an angle of 23 degrees 30 minutes, and this causes the north and south and southward apparent motion of the sun in summer and winter, thus causing the change of seasons. Nor as a matter of fact is it the case that the sun's axis is parallel to the earth's axis, nor does the plane of the earth's orbit intersect the plane of the sun's equator at an angle of 23 degrees 30 minutes. See Young's "General Astronomy," price $3, postpaid. Article 282. "The inclination of the sun's equator to the plane of the ecliptic is 7 degrees 10 minutes to the plane of the terrestrial equator it is 26 degrees 25 minutes. The axis of the sun is directed almost half way between Vega and the Pole Star." Two hundred years before Christ the Greeks had measured the inclination of the earth's equator to the plane of its orbit with a good degree of accuracy. It is half the difference of the altitude of the sun at noon on the day of the summer and of the winter solstice. It can be determined by the length of the shadow of a vertical pole at noon upon a level plane during a year. There is no reason for doubt that the position of the sun's equator in space is accurately known, and that of the earth's axis to the plane of its orbit. The seasons of the earth is a result of all this, but not a proof of this. Between these two there is a great difference.

(12481) W. P. says. Do you know of any material or composition of materials that the resistance will decrease or conductivity will increase, in proportion with the voltage or with the increasing of the voltage? I want to get some material that current will not pass through it at low voltage, but as the voltage increases, it will allow the current to pass through it. A. We do not know any material whose electrical resistance depends upon the voltage of the current to which it is opposed. Every conductor allows more current to pass as the voltage is increased, but this is not what you ask

(12482) W. G. T. says. A claims that thunder and lightning are caused simultaneously by the coming together of two oppositely charged clouds. B claims that thunder follows lightning, in that the thunder is caused by the air rushing together to fill a vacuum which has been made by the lightning's passage through the atmosphere. Who is right? A. B is correct in holding that thunder is caused by the air rushing back into the partial vacuum created by the passage of the electric discharge and the great heating of the air in the path of the discharge. The thunder is a result following the discharge of the electric strain in the air

(12483) W. C. H. asks: In your answers to questions will you kindly tell me the name of the brilliant star or planet high in southeastern sky which was passed by the moon on the evening of May 11th? Their distance apart was not over two to three degrees, I should judge. A. The planet whose name you request is Jupiter. You would be interested in following our monthly articles, "The Heavens for ————," published in the last issue each month for the following month. In these articles you will find the position of the visible planets given, so that you may always know where to look for them.

(12484) F. B. H. asks: Is there any method by which ordinary cats in periodicals can be transferred to lantern slides? A. A cut in a periodical may be transferred to a glass

plate to use for a lantern slide, by the deaf-nemesis process. Varnish the glass with a transparent varnish, and before the varnish is dry, rub the cut face downward upon the varnish. When all is dry, wet the paper and rub it off the glass carefully till all is removed and the cut is clear. If a second coat of varnish is put over the cut, probably the surface will be impaired. Any such transfer will of course ruin the cut. The best way is to make a negative from the cut, and then as many lantern slide positives may be made from the negative as you desire.

(12485) C. C. asks: Please explain whether a high-wheel wagon pulls easier than a low-wheel wagon, the wagon to be pulled by a team whose traces are horizontal and the wheels not to sink in dirt. A. On a perfectly hard surface and with frictionless bearings, the size of wheels would make no difference in the tractive force. But as such conditions never exist, the high-wheel wagon has the advantage of smaller leverage of friction and surface speed of journals, and of climbing over obstructions with a more gradual lift of the wheel and axle, and less abrupt angle of force, tending to stop the wheel in meeting the obstruction. The small-wheel system offers certain constructive advantages, lighter and stronger wheels, and no very great difference in tractive resistance on hard, smooth roads. The method of making a barometer is fully described and illustrated in SUPPLEMENT No. 909, price ten cents mailed.

(12486) R. H. S asks: I have always understood, and so taught, that the Moon revolved around the Earth once in a month, or twelve times, while we revolved around the Sun once. I saw an article that the Moon went only half way around and then returned to its starting point, and so continued. A. The Moon goes around the Earth each lunar month. It does not go half way around and then return. How could it? As well ask a base ball to stop in the air and return to the hand of the pitcher. The Moon is a heavy body in rapid motion, and cannot stop itself any more than a cannon ball can stop itself. There are, however, 12.4 lunar months and not 12 in a year, or the Moon goes 12.4 times around the Earth while the Earth goes once around the Sun. This causes the new Moon to fall in different parts of the month in the different months of the year.

(12487) W. C. F. writes: Construction No. 12456 by H. H. R. differs from that given in all textbooks for inscribing a regular pentagon in no essential feature. The line from C through the point of tangency passes through the center of the small circle, the radius of which is half the radius of the given circle. Therefore the distance from C to the point of tangency is equal to the greater segment of the radius of the given circle when divided into extreme and mean ratio, and hence equal to the side of the inscribed decagon. The rule might now be simply stated thus: Draw two perpendicular radii, and from the line joining the middle point of one to the extremity of the other, deduct half the radius of the given circle. The remaining segment will be the side of the decagon.

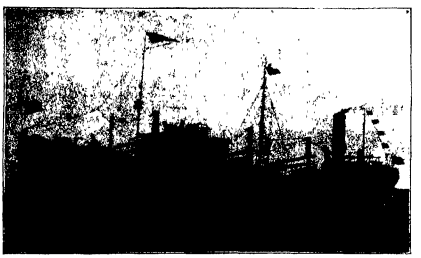
(12488) G. R. R. says: 1. How far will a 3-inch gun throw its projectile? A. 8,500 yards (this will vary somewhat with variations in the elevation). 2. How far will a 12-inch gun throw its projectile? A. 24,000 yards (this will vary somewhat with variations in the elevation). 3. How far will the new 14-inch guns (authorized for the two new battleships) throw their projectiles? A. 21,000 yards (this will vary somewhat with variations in the elevation). 4. How long is the U. S. magazine rifle bullet in the air during its maximum flight? A. The maximum range of the U. S. magazine rifle with an elevation of 45 degrees has been computed to be 5,460 yards with a corresponding time of flight of 31.36 seconds. 5. Give the penetration, in inches, through earth for the following projectiles: United States magazine rifle; field artillery; siege guns. The penetration of a magazine rifle in loam, practically free from sand, is 18.8 inches at a range of 500 yards. Simple penetrations, normal impact, for field and siege guns have not been determined. 6. Will these projectiles penetrate greater distances of earth at long distances than at short distances? A. No, because the projectiles will have a higher velocity at short distances than at greater ones. 7. What would be the probable number of transports, largest size, required to transport an army of 200,000 men from Japan to the western coast of the United States? A. Probably 100. 8. How long would it take such a fleet to make the voyage, considering that the fleet must keep together? A. The distance of the voyage would probably be about 4,800 miles, and as the fleet would be limited in its movement by its slowest vessel, probably ten knots per hour, the distance traveled per day would probably be about 240 knots. This would be on the assumption of no interference by the enemy and no accidents or other mishaps. 9. What opinion have you on the following hypothesis: Japan, without making any declaration of intention to attack any nation, commences to embark a large army of say 300,000 men on her transports at Yokohama and Nagasaki. What action would the United States take? A. As to question 9, there is no possibility of securing any serious opinion from any service man. They will not express any opinion either officially or otherwise, except in jest, such, for instance, as "issue a call for a peace conference," "call on Carnegie," and the like.

(12489) J. C. L. asks: 1. What makes this world turn on its axis? A. We are not able to say what force produced the rotation of the earth upon its axis. Its inertia in a space in which there is no appreciable resistance maintains its rotation. 2. Name two or three of the best diamagnetic substances. A. The more strongly diamagnetic substances are bismuth, antimony, tin, and copper, although no substance is as strongly diamagnetic as the magnetic substances are magnetic. 3. How far west of the true pole is the magnetic pole? Does the needle point there from any position on the globe? A. The north magnetic pole was located by the Norwegian explorer Amundsen in 1907 in latitude 75 deg. 5 min. north and longitude 96 deg. 47 min. west. The south magnetic pole was located by Lieut. Shackleton's party in 1908 in latitude 72 deg. 25 min. south and longitude 155 deg. 16 min. east. A magnetic needle at any place on the earth places itself tangent to the lines of magnetic force at that place. It points approximately in the direction of the magnetic pole, but only approximately, but it does not point constantly in the same direction. It changes from year to year. Going down into the earth to the slight distances to which we have penetrated does not affect the magnetic needle for the reason that it is below the surface of the earth. The cause of magnetism is not known. It seems to be a permanent condition of the molecule.

(12490) E. W. F. H. asks: Will you kindly inform me through Notes and Queries how many pounds (air pressure) a cylinder of steel 1/32 inch in thickness (such as seamless tubing with heads securely fastened at both ends) 2 inches inside diameter and 8 inches long, will hold with a reasonable margin of safety? If a tank is holding 50 cubic inches of air at 500 pounds pressure, how many cubic inches of air at 25 pounds pressure are contained in tank? I figure it to be 20 times 50 cubic inches, equaling 1,000 cubic inches at 25 pounds. A. Use the formula $p = 2 \times f \times s \div d$ in which

p = pressure in pounds per square inch.
d = diameter of tube in inches.
f = thickness of tube in inches.
s = tensile strength.

Thus $p = 2 \times 1 \div 32 \times 60{,}000$ and $p = 1875$ pounds per square inch. This is the bursting pressure for the cylinder if made of steel of 60,000 pounds tensile strength. You must introduce a factor of safety, which for compressed air may be 5, which gives as the safe pressure as 375 pounds. Your solution of the tank problem is correct if the pressures are absolute, or pressures above vacuum. If they are gage pressures, add 15 pounds to each to convert them to absolute pressures, and solve by proportion as before.



(12491) J. P. F. asks: I have built a store room 22 foot front and 75 feet deep, ceiling 14 feet high. Front of building is all glass with two windows in back, which gave fair light. Building is facing south, with an awning stretched over it. In the day time one can hardly see the goods in the show room from the outside, owing to the glare of light, cloudy days it is some better, there is no background to show window. Lit up at night by electric light shows off well through window. If there is any way of remedying the trouble you will confer a favor by helping me out. As we are not quite clear as to the arrangement of the show window and store, but it is apparent that you need a background in the window to throw back the light on the goods behind the glass. The background need be only 4 to 6 feet high, so that light will pass over it into the store behind. If the store lighting is bad with the background in place, prism glass in the upper part of the window will project the light back sufficiently.

(12492) F. E. L. asks: Can any two or more chemicals, either liquid or dry, be brought into contact (not forcibly) and cause a quick combustion? A. There are a good many substances which take fire upon coming into contact. The end of a match and sandpaper, the safety match and the side of its box are examples. Phosphorus and iodine will ignite by mere contact without friction or pressure. 2. Are there any chemical substances which upon being exposed to the air will burn almost instantly? A. Hydrogen and chlorine gas mixed in equal parts will explode by letting the sunlight fall upon them. Impure hydrogen phosphide gives a very interesting case of spontaneous combustion when it escapes into the air. 3. Are there any chemicals which upon being exposed to certain gases burn almost instantly? A. Finely divided phosphorus will take fire almost instantly when it comes into contact with the air. These and many other chemical experiments of equal interest are described in Bendier's "Chemical Lecture Experiments," which we will send for $2 by mail. No such experiments should be attempted without special precautions against flying glass or fire, except by a person already experienced in chemical manipulations. They are not adapted to a careless amateur.

DIVINE WATER MOTOR CO.
DEPT. 1 UTICA, N.Y.

NEW BOOKS, ETC.

ENGLISH FURNITURE. By Frederick S Robinson London: Methuen & Co. Large 8vo, 365 pp 160 plates.

This sumptuous volume belongs to the connoisseur's library. The book itself is beautifully gotten up and is elaborately illustrated, although we must admit we do not like massing all of the plates at the back of the book, which would be much more usable if they were interspersed among the text; still it is almost a pity to criticise such an illuminating and informing book. English furniture at the present date supplies one of the most interesting links for the collector, and the aim of this book is to assist those who collect or who purpose collecting. The subjects of the plates show a tendency to avoid the more common styles, but give a few of the general types with which a collector may meet. A false idea of English furniture would be formed if a majority of the plates reproduced were only such as are seldom or never found for sale but at the same time serve as examples of the skill of the old cabinet maker. Reproductions from the pattern books of Chippendale and his successors have been avoided. The book will be of great use to those who are not versed in the study of English furniture. Chippendale, Manwaring, Ince, Mayhew, Adams, Sheaver, Heppelwhite, and Sheraton are almost household names in this country as in England. Typographically the book is one of the best that we have seen for a long time.

THE FURNITURE OF OUR FOREFATHERS By Esther Singleton With critical descriptions of plates by Russell Sturgis New York, Doubleday, Page & Co., 1908. 8vo, 664 pp $6 net.

There are happy hours before the old furniture enthusiast who picks up this fine collection of plates with the accompanying text giving wonderful inventories of household goods, stories of the belongings of notable personages, and descriptions of the crowding with the useful and often highly ornamental chattels of vanished days. Part I dealing with early Southern furniture, presses upon our notice a wealth of industrial pieces taken rabbits showing Flemish influence, walnut chairs with baluster-shaped legs and arcade-pattern backs, tables and cupboards of oak with the carvings fluttings and linked designs common to the period. Next we see a cradle, too, from an old Worcestershire manor house, with punched hood and cushions of figured velvet. In later Southern furniture we are presented with examples such as William Penn's desk, a quaint chair used by Thomas Jefferson when writing the Declaration of Independence the reading desk of John Dickinson, and a library chair belonging to Benjamin Franklin the seat of which is oblong; tips to form a step under. Part III continues the list with early New England and the imported and home-made pieces of the seventeenth century. Part IV gives us the Dutch and English periods, with church stools warming pans, kas, or mammoth chests and cupboards, fine examples in marquetry chairs from the Gansevoort and Schuyler families, and hall clocks of quaint design. Part V summarizes the work of the eighteenth century, with its beautiful sofas, tables, and chests of drawers. Part VI is devoted to Chippendale, and the plates show most beautiful examples in cabinets, chairs, lounger in bloc, settees and mirrors. Parts VII and VIII continue the history of furniture through the early part of the nineteenth century and quite fulfill the expectations aroused by the foregoing sections of the work. A mere enumeration of the most striking features can not do justice to the work as a whole. It is one to be fingered over, and returned to time and again.

PEUT-ON VOLER SANS AILES? By Paul Collard Paris: Librairie Aéronautique, 1911 8vo, 109 pp., illustrated

Here we have exploited a new type of heavier than air flying machine, designed to shift the burden of support from wings to propeller. This result is brought about by an upward inclination of the propeller shaft. The inventor names his conception the "Aerobil," and claims for it many advantages over the spread-angle aeroplane at present in vogue. The theories and results are impressed upon us by reiteration and are even reduced to formulæ. Among other virtues the security is that of a level landing instead of the head on approach to earth now made necessary in bringing an aeroplane to the ground. Provision is made for safe alighting in case of engine failure, and the transverse stability of the Aerobil is supposed to be to a great extent automatic. The inventor is very much in earnest and writes with the sincerity of conviction.

THE WORLD WIDE ATLAS OF MODERN GEOGRAPHY, POLITICAL AND PHYSICAL Introduction by J Scott Keltie, L.L.D., Edinburgh and London W. & A K Johnston, Ltd., 1911 Small 4to; 128 plates and 98 page Index Price, $3

It is astonishing to see what a very usable atlas can be obtained for such a moderate sum. The publishers are known for the quality and accuracy of their work. The maps are clear, not overburdened with too much detail and show every indication of being thoroughly up to date. The production of an atlas is a serious and expensive undertaking, and atlas makers of this country have much to learn from British and German map makers, particularly as regards size. This atlas is small and light in weight, but is fully as informing as many American atlases of three times the superficial area. The United States is very apt to be neglected in such foreign works of reference, but it is not in the present instance. The South American maps are especially good. British possessions all over the world are admirably treated.

LE CONSTRUCTEUR DE CERFS-VOLANTS 1 re Serie Cerfs-Volants simples. G. Dubouchet et J. Frotche. Paris: Librairie Aéronautique 8vo.; 24 pp.

Kite flying is one of the most ancient and honorable divisions of mankind, and the fact that the modern aeroplane partakes very much of the nature of a motor-driven kite lends new interest to an old pastime. This pamphlet is the first of a series on kite construction, and contains folders which show plans for four of the simplest kites known—the tear-shaped, the hargrave, the hexagonal, and the oblong. Very plain instructions accompany the drawings.

ANCIENT MYTHS IN MODERN POETS. By Helen A. Clarke. New York Baker & Taylor Company, 1910. 12mo.; 360 pp Price, $2 net.

A beautifully printed and most beautifully bound book, well illustrated "The Prometheus Myth from Hesiod to Shelley" and "The Moon and the Sun from the Homeric Hymns to Keats" is the full contents. The author has written "Hawthorne's Country", "Browning's Italy", "Browning's England", "A Child's Guide to Mythology," and "Longfellow's Country," which show an appreciation for some of the fascinating phases of literary environment. Several of the illustrations are taken from the paintings of Max Klinger and one from Watts, both strong portrayers of the poetic side of myths. The binding is particularly handsome, showing a judicious combination of colored leaf and gold.

ENGINEERING LAW VOL. I THE LAW OF CONTRACT By Alexander Harding, C.E., LL.B., LL.M. Chicago 1911, The Myron C. Clark Publishing Company, 1910. 8vo, 518 pp Price, $4 net.

As is indicated by the title of this volume, the book is intended particularly for the use of engineers and engineering students. It presents a condensed text of the law of contract as applied to engineering, or rather as the law of contract has been developed in connection with cases and adjudications in solving engineering subjects. The underlying principles of the law of contract are of course the same as those which applied by or to the engineer, or otherwise. Consequently, the author has properly sub-divided the subject, and in each sub-division sets forth concisely and logically the principles then under. At the end of each sub-division were given numbers of cases exemplifying the principles and showing their application to engineering. The authors purpose in writing this volume of his work is to give the student as well as the practicing engineer, an understanding of the subject sufficient to guide him in meeting the legal phases of whatever branch of engineering may be the field of his activities. As stated in the preface, the author does not believe that the case system of teaching law is the best one for engineering, and that on the other hand the text-book method alone, does not enable the student to understand fully, how the courts work out the rules of law in connection with concrete facts. As a result, he has combined, and most judiciously, the two methods as stated above. This volume of engineering law will prove useful not only as a text book, or for use in connection with lectures in technical schools, but also as a work of reference for the practising engineer.

THE DAWN OF MEDITERRANEAN CIVILIZATION By Angelo Mosso Translated by Marian C Harrison New York. The Baker & Taylor Company, 8vo; 424 pp, 203 illustrations. Price, $4 net.

The fascination of prehistory, as Prof Mosso calls it, clings to these pages in no small degree. Things which most men would pass by as broken pottery and decaying bone are made to yield up to us a story of life in prehistoric times telling us of the beliefs observations, customs, and passions of bygone races, and leaving us with that feeling of renewal and regeneration which comes of contact with childhood in any form, racial or individual. In other words, far from feeling that we have made a journey into the grave, we are given a new strength and clearness of vision which enables us to see more vital things. The reader accompanies the author upon his expeditions, participates in the joy of his discoveries, and follows him as he reasons back from the physical features of his find to the mental characteristics which determined them. Who can hear mention of such topics as the origin of writing, the origin of art in religion, the coloration of the body, or pre-Homeric navigation, without being at once eager to know what research teaches us of them? And when, as in the present instance, inscriptions and weapons and carvings are put before us in such profusion, and the argument from them back to their makers is so simply stated, we can not but feel something of the thrill of discovery which energizes the writer and en-

THE L. S. STARRETT CO., Athol, Mass., U. S. A.

styles him to give vitality to the past through the medium of the printed page. This well-made and attractive volume is the second of a series of three, the first dealing specifically with the subject of the excavations in Crete.

THE GARDEN MONTH. Describing the appearance, color, dates of bloom, height, and cultivation of all desirable hardy herbaceous perennials for the formal or wild garden, etc. By Mabel Gabot Sedgwick, assisted by Robert Cameron New York: Frederick A Stokes Company. 8vo.; 516 pp.; Illustrated Price, $4.50 net

All the scattered lore of floral catalogues, magazines, and handbooks seems to have been brought together here in most attractive and helpful form, with the addition of much that it would be hard to find elsewhere. To begin with, there is a large color-chart showing the tints of flowers and naming and numbering them, so that in the descriptive lists following the exact color of any flower may be determined by a reference from the tint number there given to the same number on the chart Sharp line drawings are interspersed showing the more noteworthy plants and blossoms. There are also descriptive lists of water plants, of foliage plants of vines and climbers, and of ferns An index of both botanical and English names furnishes ready access to any required information In the main body of the work each page is headed with the name of a month and is divided into six columns In the first column is the color-number of the flower in the second its English name, in the third its botanical name The fourth column contains a brief description of its appearance, often with a reference to an excellent illustration, the plant with which it is best suited—the rock garden, the border, the ornamental bed; its mode of propagation, the soil which it requires, and other notes of interest The fifth column states the height to which it grows, and whether in sun or shade The last column states the time of bloom Many disappointments and mistakes may be avoided by a reference to this compendium By its use in conjunction with the color-chart, the gardener *may* visualize his proposed color scheme and make sure that his floral picture, when finished will be artistic and satisfying

THE AUTOMOBILE. Its Selection, Care and Use. By Robert Sloss. New York Outing Publishing Company, 1910 12mo , 194 pp Price, $1.25.

Like Tennyson's brook, the stream of books designed to aid a man in choosing and running an automobile bids fair to go on forever What do I want to use my car for? is the question the would-be purchaser is urged to ask himself. And upon the answer to that question and the nature of the roads over which the car must be driven, depends the future satisfaction and comfort of the hero in his new acquisition The chapter on 'mechanical tips' puts the reader in possession of much information that may save him from the misleading statements of agents and qualify him to judge intelligently of the attributes and possibilities of the car he is trying out. The sections on "the care of your own auto" and "driving with brains" continue to furnish knowledge that the tyro must sooner or later acquire, if not by previous study, then by hard experience Trouble-finding and the care of tires, with the use and equipment of the car on tour and in camp, bring to a conclusion the brightly written little treatise

THE ELEMENTS OF GRAPHIC STATISTICS By William Ledyard Cathcart and J Irvin Chaffee, A M. New York. D Van Nostrand Company, 1910 8vo , 312 pp , 159 illustrations Price, $3 net

"Graphic Statics" is a survey of the field of balanced forces, in which geometrical constructions are used instead of algebraic analyses. By this method it is possible to represent the magnitude, direction and point of application of a force by the length, inclination and position of a simple straight line. The gain in conciseness and ease of demonstration is apparent After expressing the principles of graphic arithmetic, the authors turn to studies of forces and moments, the fundamental laws of tension, compression and reaction as applied to beams; roof trusses; bridge trusses; and the graphics of friction The work is particularly addressed to students of marine engineering and naval architecture, and the principles of graphics are shown in their application to mechanisms as well as to framed structures. The final section of the volume presents a series of moment diagrams for shafting, with test problems appended.

APPLIED THERMODYNAMICS FOR ENGINEERS. By William D. Ennis, M.E. New York: D. Van Nostrand Company, 1910. 8vo.; 438 pp.; 216 illustrations. Price, $4.50 net.

The shortest for supremacy between the steam engine, the gas engine, and the turbine furnishes one of the most stimulating spectacles of modern progress. The advantages and drawbacks of each, with the determined efforts of engineers and inventors to increase the one and reduce the other, leads us into a competition that at least results in pushing forward the efficiency of the prime mover in a field of its own work and recreation of the world. The text-book in hand maintains that thermodynamics is neither mathematics nor logic, but physics, and hence should be presented in a middle course that proceeds from ideal operations to their modification in practice, with the development of underlying principles—stopping before these principles harden into machine design Sound theory is given precedence over rules of practice so that the student may first acquire a confident grasp of underlying laws which will enable him to attack new problems successfully, varying his rules to meet the exigencies of the particular problem in hand The cuts and diagrams are plentiful and clear Problems are appended to each division of study so that their working out may lead to a perfect understanding of the preceding lesson Chapters on compressed air and mechanical refrigeration are incorporated, and the gas producer receives its share of attention

THE ELECTRICAL NATURE OF MATTER AND RADIOACTIVITY By Harry C Jones New York: D Van Nostrand Company, 1910. 8vo ; 210 pp Price, $2 net

Some years ago a series of articles appeared in the *Electrical Review*, dealing with these two correlated subjects It is this series, revised, and with the more important of the recent discoveries added, which forms the volume in hand The leading facts and deductions are presented in language as free as possible from mathematical terms A popular elementary dissertation and treatment has been the aim, without any sacrifice of accuracy There are chapters on the nature of the ion *inside* and of the atom, on the radioactive substances in pitchblende and the properties of radiations, on the production of radioactive matter, and on theories and generalizations

THE FINE ART OF FISHING By Samuel G Camp New York Outing Publishing Company, 1911 12mo., 177 pp Price, $1 net

This attractive little brochure is in essence and in name a reminder of H P Wells's declaration that the angler considers his sport as a fine art, of which merely to obtain fish is a small part It is the way the thing is done" In Fishing Kits and Equipment the writer described the mechanical means of casting for fish In the present papers he concerns himself rather with the approved methods of using these mechanical means Since the methods must vary with the kind of waters fished and the kind of fish sought, the papers resolve themselves into discussions of our common game fish and their haunts, with the most approved usage in fly and bait casting The numerous plates are for the most part inspirational rather than daily instructive, and a vein of catching enthusiasm runs through every chapter

SOCIALISM A Critical Analysis By O D Skelton, Ph.D New York Houghton Mifflin Company, 1911 8vo , 329 pp Price, $1.50 net

In a contest inaugurated by a Chicago firm, this analysis of socialism was awarded first prize The introductory chapter wisely refrains from any attempt at a final definition offering instead a brief historical survey of socialistic systems past and present The indictment against capitalism is then set forth its exaggerations and lack of perspective pointed out, and the impossibility of a lawless order is urged Socialistic views are given over to the Marxian system—the materialistic conception of history, value and surplus value, and the law of capitalist development The modern socialistic ideal is summarized in so far as the writer can give it form, and the socialist's attitude toward industrial and other problems is analyzed as fluid, if not vaporous That is the socialist refuses to submit published plans for his ideal order and revolts against the tyranny of detail The writer has at least succeeded in placing in a high light the complexity of the factors entering into the question, and his canvass is not lacking in interest, although he seems to be almost personal conviction and his tentative setting forth of possibilities can hardly be dignified by the name of conclusions As an analysis, the essay is comprehensive, as a critical estimate it is barren of results

THE BOY SCOUTS OF THE EAGLE PATROL By Lieut Howard Payson New York Hurst & Co 1911. 8vo , 302 pp. Price 60 cents

The essential elements of the plot are provided by a trio of youthful criminals who seem to regard burglary and kidnapping as huge jokes Their schemes are directed against the boy scouts in revenge for imaginary slights, and they are assisted by a disreputable old reprobate who has served time in jail for smuggling The chapters in which three of the scouts are towed out to sea by a shark lost in a thunder squall, and almost run down by a liner, have enough incident in them to satisfy the strongest craving. Aside from the quarrelsome blackness of two of the young villains, which has been put on with rather too thick a brush, the story is well-calculated to make a host of boy friends and to inspire them with courage and a desire to learn something of woodcraft, telegraphy, and aeronautics

VOZDEI FREMDER LANDER. Von Dr K. Floericke. Kosmos Gesellschaft der Naturfreunde. Stuttgart: Franckh'sche Verlagshandlung.

1895 Seventeenth Annual Announcement 1912

Columbia with Silent Knight Motor

BELIEVING that the Knight Motor supplies the greatest measure of Power, Flexibility and Silence in gasoline engines of high power as evidenced by its successful use by the foremost builders of Europe including among others the ENGLISH-DAIMLER, MINERVA, PANHARD-LEVASSOR, MERCEDES,

we are now pleased to announce that we have secured for America, license to build Columbia cars equipped with this now world famous

SILENT KNIGHT MOTOR

Catalog and other descriptive literature mailed on request

"MACK"
LEADING GASOLENE TRUCK of AMERICA

AS builders of motor trucks exclusively, it is only reasonable for you—as a prospective buyer—to expect the maximum of value, long time service and all around satisfaction in the "Mack" Truck. It will perhaps further influence your decision to know that over 1200 "Mack" Trucks are now in actual operation, with the strongest of commendatory letters from each owner on our files. We build the "Mack" in from 1 to 7 tons capacity, to conform to your own special requirements. Our new highly illustrated catalog should be in the hands of every intending purchaser It's mailed free, write to-day.

Let Us End That Corn

A bit of soft B & B wax, which we put in a plaster has ended fifty million corns.

The plaster is applied in a jiffy, and the pain of the corn stops at once. You simply forget it. Then the wax gently loosens the corn, and in two days it comes out. No soreness, no feeling whatever.

The plaster is called Blue-jay. Its sale is larger, by fifty times over, than for any other corn application. Learn why. It is utterly needless to be pained by a corn.

A In the picture is the soft B & B wax. It loosens the corn.
B protects the corn, stopping the pain at once.
C wraps around the toe. It is narrowed to be comfortable.
D is rubber adhesive to fasten the plaster on.

Blue-jay Corn Plasters

Also Blue-jay Bunion Plasters
15c and 25c per Package

Merchant Marine as an Auxiliary to the Navy

(Continued from page 50.)

that an adequate merchant marine can be built up by subsidies and discriminating duties jointly. With two means available of accomplishing a desired result, it is a sad commentary upon our practical statesmanship if our people cannot get together upon some measure of relief. In default of this we are guilty of deliberately perpetuating an endless procrastination, for which the foreign shipping interests are the most greatly obliged, to say the least. In the meantime, let us be prepared for the usual tirade against subsidies, accompanied by descriptions of the splendid imaginary shipping of the free-ship fallacy from anonymous newspaper articles and stuffed editorials, interposing all possible obstacles in the way of any legislation which shall wrest from the foreign shipping companies that portion of our own commerce which we must necessarily possess in order to control our own ultimate destinies.

Present Status of Cancer Research

(Continued from page 49.)

cancers and by special methods of examination peculiar bodies have been shown to exist in cancer cells, and these various parasites have been considered to be the cause of cancer. These parasites have been injected into animals in order to produce cancers, but as yet apparently no true cancers have been noted as a result of these injections. In many cases collections of new formed cells have developed, but as a rule these have not shown the distinct characteristics of a cancer, and the possibility exists that the development of a cancer in an isolated case when an animal has been injected with various micro organisms may possibly be due to the spontaneous development of cancer independent of the injection of the micro-organisms.

As to the possible influence of pure chemical or physical factors upon the development of cancer or the growth of cancer cells, we possess certain observations. Thus it has been shown that the activity of inoculated cancers may be experimentally increased or decreased by the action of these agencies. When tumors are heated for various lengths of time their power of growth is diminished. When they are subjected to a constant irritant, the power of growth is increased. In a similar manner the action of certain chemicals may decrease the activity of proliferation of cancer cells, on the other hand in animals fed with certain substances the rapidity of growth of inoculated cancers is increased. In this respect the conditions influencing the growth of cancers are similar to those which act in the case of normal tissue, and it is being recognized more and more that the study of normal tissue growth will throw light on the questions of cancer growth, and that a study of cancer growth may clear some of the questions of tissue growth.

That chemical stimuli may influence the proliferation of normal cells has been shown in certain cases. Thus when certain chemicals were injected under the skin of rabbits it was noted that the cells of the skin took on an increased power of growth, thus were stimulated by these chemicals. However, it has not been possible to produce a cancer by this means.

Distinctly suggestive are the results of experiments which have shown that under certain conditions, namely, when certain tissues had been sensitized or prepared by being acted upon by specific substances found within the body, the action of a mechanical stimulus was sufficient to cause those sensitized cells to proliferate rapidly. While in these cases a true cancer was not formed, since all growth ceased after a certain period of time, we have at least the experimental evidence that under certain conditions sensitization may so influence cells as to cause after the action of a mechanical stimulus a marked increase in their proliferative power.

The study of cancer in lower animals has given great opportunity to test various methods for either curing or preventing cancer. As yet no method to cure cancer has been found. Neither treatment with drugs nor serum (especially prepared in order to destroy cancer cells) nor with so-called vaccines[1] has been able to check the growth of a cancer when once it has started to grow.

On the other hand definite results have been obtained as regards rendering animals resistant to cancer. In animals in which a cancer has been inoculated, it is occasionally noted that the implanted cancer grows for a short period of time, but later becomes smaller and disappears. When such animals are inoculated with cancer a second time, in the majority of cases the cancer cells do not grow, such animals are said to be immune or resistant to cancer. It may, however, be noted that occasionally when these animals are inoculated a third or a fourth time, the cancer may grow so that apparently this resistance to cancer is not absolute in every case.

Furthermore in certain cases when relatively large quantities of cancer material were injected, and did not grow, many of the animals so injected were resistant to a second inoculation of cancer material. It has likewise been noted that where normal tissues of mice, such as liver, spleen and blood cells were injected into other mice, the subsequent inoculation of cancer cells does not lead to the formation of a cancer.

It has also been shown that when animals are treated with cancer cells whose activity has been lessened by experimental means, that these animals became under certain conditions resistant to a second inoculation of cancer, so that no growth results.

It may be noted that in every one of the instances cited above, living cells have been used in order to render the animals immune to cancer. The inoculation of dead cells apparently cannot lead to the immunization against cancer.

The knowledge that a previous inoculation of animals with either cancer material or normal cells caused such animals to become resistant to cancer led to attempts to cure cancer in human beings by similar methods. Cancer cells which had been ground to a very fine pulp were injected into persons suffering with cancer; in a few cases the results of such injections appear to have been beneficial, but from the data on hand at present it seems doubtful that this treatment is curative.

Various investigators who adhere to the belief that cancer is caused by micro-organisms have advanced other methods for treating cancer. Thus sera have been prepared which were intended to destroy the parasites or neutralize their poisons. These sera have been used in treating animals suffering with cancer. Other investigators have attempted to cure cancer by injecting the dead organisms which they have considered to be the cause of cancer. The consensus of opinion as regards these methods of treatment is that they are scarcely likely to prove successful, for, if cancer be due to a parasite, we have still to discover what that parasite may be.

It may be stated that in various animals which have been inoculated with cancer and in which the cancer grows for a short time but later disappears[2], it has not been possible to demonstrate any substance in the blood which would delay or prevent the growth of cancer in another animal. This absence of an anti-cancerous substance in the blood of animals which have recovered from cancer would appear to differentiate cancer from the most of the diseases caused by micro-organisms; for in most infectious diseases one finds in the blood of individuals who have recovered from an attack, substances which either prevent or minimize the severity of a second attack or which destroy the organism causing the disease. Therefore it would appear that the cure of cancer will not be found by pursuing the same lines of research as were and are being followed in seeking cures for the diseases caused by micro organisms.

In considering the various treatments of cancer which have been tried within the last few years, at least a passing word must be said anent the use of the X-ray.

[1] The vaccines used in treating cancer are analogous to small-pox vaccine, and are composed of substances extracted from cancer cells, or of cancer cells whose power of growth has been experimentally weakened.

[2] There is a distinct difference between inoculated cancer and spontaneous cancer; a certain percentage of cases of inoculated cancers show this retrogression; spontaneous cancers, however, very rarely retrogress.

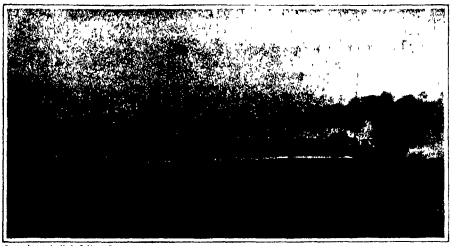
and radium. Both of these have been tested upon human beings, and upon animals, and although in a few cases they appear to have cured cancers, it is evident that in the majority of cases they are not effective. Their action depends upon certain rays of light which kill the cancer cells, and while they frequently are effective in destroying such cancers as originate from cells of the skin, which are superficial and accessible to these rays, naturally these rays cannot penetrate and destroy cells of cancers which are within the body.

In a certain small number of cases of cancer in human beings it has been noted that the tumor ceases to increase in size, then grows smaller and finally disappears In one such case, following the spontaneous cure of a cancer in the abdomen, there developed in the peritoneal cavity a collection of fluid similar in character to the collection of fluid noted in kidney or heart disease. This fluid was withdrawn from the abdomen of the cured individual and was injected into persons suffering with cancer (it was hoped that this fluid might contain anti-cancerous substances). While in some cases the injection of this fluid seems to have benefited the patients, it does not seem probable that this method of treatment will prove to be of curative value.

Modern experimental investigation has therefore not as yet shown the cause of cancer. It has, however, definitely shown that the problem of cancer is intimately related to the problem of cell growth, and it is along this line that future work must be directed. As to whether the primary cause of cancer be a micro-organism or whether we must look to some change in the nature and function of the cell itself for the explanation of the origin of cancer, we are not in a position to state.

Nor has any successful treatment for cancer as yet been found The use of specially prepared sera containing anti-substances which either destroy the cancer cells or the parasites which are supposed to be the primary cause of cancer has not been successful Nor has the use of various chemical substances or various kinds of light rays

However, within the next decade our knowledge of cancer should be largely increased. At present there are in the United States five laboratories or funds which are working especially in the search for knowledge regarding cancer; thus at Harvard University there is a department for cancer research, at Buffalo there is the State Cancer Laboratory, at Columbia University special work is being pursued under the auspices of the Crocker Cancer Fund. At Cornell University Medical School also a special fund exists. In St. Louis the Department of Pathology of the Barnard Free Skin and Cancer Hospital is concerned almost entirely with investigative work along the lines of cancer research At the Rockefeller Institute also cancer research is done



In England under the Imperial Cancer Research Fund, which has large means at its disposal, experimental and statistical work is conducted. In Berlin there are two special institutions for cancer research In Heidelberg, in Moscow, and at the Pasteur Institute in Paris, work is being conducted. Besides the investigators working in these special laboratories, there are many individual investigators both in this country and abroad who devote much or all of their time to this subject. In addition to these laboratories there are several hospitals, in some cases connected with the laboratories, which treat only cancerous cases.

Now that the fight against tuberculosis is well established both in lines of scientific research and in efforts toward public education and that it is generally recognized that scientific research will gradually add to our already acquired knowledge of how to control and cure the various infectious diseases, there still remains the crying need for support for investigative work in the lines of cancer research. For cancer is certainly one of the diseases which human beings have most to fear both on account of the inability to cure (except by early excisions) and the frequent occurrence of this disease. The endowments and financial means at the disposal of these laboratories mentioned above during considerably less than the largest of them have really ample means to carry on the work on such a scale as it should be carried. It will only be by placing sufficient means at the disposal of the various investigators that we may hasten the eventual success of the research as regards the cause and cure of cancer.

Weather Insurance

INSURANCE against bad weather is just now the subject of much discussion, *pro* and *con*, in the English newspapers and scientific journals. Two articles on this question appear in the April number of *Symon's Meteorological Magazine*. Dr. Mill, the editor, quotes from *The Times* the prospectus of the Excess Insurance Company, Limited, which offers four forms of rain insurance policy, known as Pluvius "A," "B," "C," and "D." The first provides for compensation in case within a specified week there are more than two days on which rain falls to the amount of over 0.20 inch. The premium is one-eight of the weekly compensation, thus, £1 per week premium would bring £8, in case the limit of rainfall was exceeded within the week Pluvius B provides for payment for every day on which the rainfall exceeds 0.20 inch, and the premium per week is one and one-half times the compensation payable per day Pluvius C takes account of smaller falls of rain, and offers compensation for the second and each additional "rain day" (a day with 0.01 or more of rain) in every separate week having a total rainfall exceeding 0.15 inch. The premium per week is equal to the amount payable per day Pluvius D provides for four consecutive days, and under it payment will be made for every day on which the rainfall exceeds 0.20 inch The premium for four days is equal to the compensation to be paid per day. Proposals for policies A, B and C must be made at least seven days, and for policy D at least two days before the period begins.

It is pointed out in one of the articles referred to that the term "compensation" is inappropriately applied to the money that the company will be required to pay in the event of a certain contingency that may not involve a loss, pecuniary or otherwise, to the insured A man residing in London, for instance, may take out insurance against the occurrence of rain at Liverpool during a certain week, though he may have no intention of visiting the latter place and the rain that may fall there may in no way affect him In this case the transaction becomes a pure gamble Supposing, however, that the policyholder is really seeking to indemnify himself for a spoiled holiday—or for the loss of gate-receipts at some out-of-door entertainment of which he is the promoter—the vagaries of a rain storm may defeat the best intentions of both insurer and insured. The policy provides that, within a certain district, the readings of a specified raingage shall determine whether the company is liable for the amount of the policy However, rain is often so local a phenomenon that the gage may record a heavy shower when the policyholder, a few miles or even a few rods away, may not experience a sprinkle In this case he collects his insurance though he has suffered no damage On the other hand, he may get a drenching from a local storm that does not contribute a drop of water to the gage, thus suffering damage for which he is entitled to no compensation This is but one of the elements of uncertainty that enter into the question the plan assumes, for example, a much higher degree of accuracy in rainfall measurement than should be expected of the average observer If the total rainfall up to the moment of observation is near to the critical amount, the observer's personal equation may easily vitiate the result. A rain gage is rarely read exactly at the nominal time of observation; and a deviation therefrom of a minute or two, if heavy rain is in progress at the time, might threw the measurement one side or other of the critical value. Even the question of disposing of the third decimal, where the gage is read to the thousandth of an inch—a matter of no importance from a scientific point of view—might involve the loss of

CONSERVATION

The AUGUST MAGAZINE NUMBER of the SCIENTIFIC AMERICAN

ISSUE OF AUGUST 12th, 1911

"The average American family throws out of the back door enough food to feed an average family in Europe." Yes—you have heard that before—so often have you heard it that you are weary of the repetition. Yet your ear is not half so tired of the sound as your heart should be sick of the fact. We are an amazingly wasteful race. Our garbage-pail and waste-basket, full as they are to overflowing, have grown to a size which is a national reproach. Our "dime" is the "penny" of those older races that have learned the lesson of thrift under the lash of poverty—our "dollar" is their "shilling"; our "millionaire" their man of "modest fortune."

The next magazine number of the Scientific American, August 12th, 1911, will contain a series of articles by leading authorities, which will deal with this vital subject of the conservation of our natural resources.

Ex-Chief Forester the Hon. Gifford Pinchot, whose earnest fight for the preservation of the coal lands of Alaska has led to a favorable decision of the Land Office, which greatly strengthened the cause of conservation, will open the number with an article on the Conservation of our Forests.

The Director and Chief Engineer of the Reclamation Service, F. H Newell, will write a general article on the past work and future plans of the Reclamation Service. In its freedom from political interference and the high professional character of its personnel, and in the permanent nature of its engineenng work, this branch of our national conservation is deserving of the highest praise. Mr. Newell's article will be supplemented by several others written by the Resident Engineers in charge of the principal projects.

The Director of the Bureau of Mines, Dr. Joseph A. Holmes, will show that the waste of our supplies of coal is due not merely to careless and extravagant management in the mining of the coal, but also and very largely to methods in burning the fuel. Poorly designed furnaces and badly constructed smoke-stacks, which inevitably result in excessive smoke production, are answerable for much needless waste of coal.

Dr. David T. Day, of the United States Geological Survey, will prove, in an article on the conservation of oil and gas, that, as with coal, so with oil and gas, it is possible to effect large economies by judicious management in the oil and natural gas fields and by the use of improved appliances in burning these fuels either for light or power purposes.

Dr. Hugh M. Smith, Deputy Commissioner of Fisheries, will contribute an article on the Conservation of Fish, Oysters, etc., and Seals. Conservation is a word to which we are liable to give too restricted an application. We are apt to think in terms of forests, mines and other resources strictly related to the land, forgetting that the food supplies in the seas and rivers are subject to as ruthless a waste and call for as careful a conservation as any of the resources of *terra firma*

In addition to the above articles, the August 12th number will contain the usual Editorial, Aviation, and other Departments.

thousands of dollars to the insurer or the insured

To the meteorologist the whole scheme appears to border on pure speculation, and not to be reducible to the scientific character of ordinary forms of insurance There does not appear to be any attempt, even, to take into account the geographical and seasonal distribution of rainfall The projects of this character thus far put forth apparently assume that the risk is the same whether the place covered by the insurance has a mean annual rainfall of 25 inches or 50 inches, and whether the period in question falls at a time of year that is usually dry or the reverse

The complications involved in formulating a really equitable scheme of insurance against rain are so numerous that no actuary having a moderate knowledge of meteorology would think of trying to solve the problem.

Dreams That Came True

A PROVERB, which by constant reiteration has become somewhat musty, tells us that "Truth is stranger than fiction," and we have constant evidence of this outstripping of romance by reality It is not so generally known that romance has often anticipated sober fact; but such is the case In the present article it is proposed to enumerate a few instances which appear o be of unusual interest

In the year 1869 the Suez Canal, one of the most important engineering enterprises ever undertaken, was opened to the world's traffic. It was foreshadowed as long ago as the sixteenth century by Christopher Marlowe, one of the early English poets, in the following lines:

> Thence marched I into Egypt and Arabia,
> And here, not far from Alexandria
> Whereat the Terrene and the Red Sea meet,
> Being distant less than full a hundred leagues,
> I meant to cut a channel to them both
> That men might quickly sail to India."

It may be urged with reference to this quotation that so soon as it became possible to make an approximate y correct chart of the world the advantage of cutting through the Isthmus must have been apparent to many, and that Marlowe merely reflected the thought of others This, of course, is likely to be the case; but no such plea can be urged against the very curious anticipation of wireless telegraphy by Strada, the Italian historian, who was born at Rome in the year 1572 Addison quotes Strada in one of his noted essays, but we need hardly say that in doing so he had no notion of any anticipation of the electric telegraph, for Addison died just a century before communication by that means became possible Addison writes thus:

"Strada, in one of his prolusions, gives an account of a correspondence between two friends by the help of a certain lodestone which had such virtue in it that if it touched two several needles when one of the needles so touched began to move, the other, though at never so great a distance, moved at the same time and in the same manner He tells us that two friends, being each of them possessed of one of these needles, made a kind of dial-plate, inscribing it with the four-and-twenty letters, and in the same manner as the hours of the day are marked on the ordinary dial-plate. They then fixed one of the needles on each of these plates in such a manner that it could move round without impediment so as to touch any of the four-and twenty letters Upon their separating from one another into distant countries, they agreed to withdraw themselves punctually into their closets at a certain hour of the day, and to converse with one another by means of this, their invention . . By this means they talked together across a whole continent, and conveyed their thoughts to one another in an instant over cities and mountains, seas or deserts."

It will be seen how close is the description of this dial instrument to the A B C telegraph of Wheatstone which, until it was superseded by the telegraph, was in common use in many offices. But as there is no mention of any conducting wires between the two friends in communication, we are justified in regarding this as being prophetical of the more recent invention of Marconi.

Roger Bacon (1214-94) may have foreseen the possibility of making dynamite and other powerful explosives when he wrote the following words:

"A small portion of matter, about the size of the thumb, properly disposed, will make a tremendous sound and coruscation, by which cities and armies might be destroyed." But he does not go so far as to hint that it would ever become possible to throw small parcels of explosive matter upon a doomed place from a distance of seven miles or more, a terrible example of the power of propellants which was witnessed in the war in the Far East

The torpedo was very well described by Ben Jonson three hundred years ago, as the following bit of dialogue, taken from his "Staple of News," produced in 1625, will show:

"Barber. They write here of one Cornelius-son hath made the Hollanders an invisible eel to swim the haven at Dunkirk and sink all the shipping there

"Pennyboy But how is't done?

"Cymbal I'll show you, sir. It is an automon, runs under water, with a smug nose, and has a nimble tail made like an auger, with which tail she wriggles betwixt the coats (ribs) of a ship and sinks it straight.

"Pennyboy A most brave device to murder their flat bottoms."

No doubt, however, can be entertained regarding the reality of the various devices described and illustrated in the work by Hero of Alexandria, who flourished about 100 B C In this book may be found the prototype of the steam turbine, the form of engine that has come to the front within the last few years.

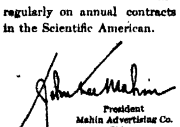
Turning over the pages of Heron's work, we are reminded that the slot machines which seem to us moderns such a new way of dispensing small articles are by no means new in principle Here a machine is described and figured which is provided with a slot, the dropping of a coin within which will cause a measured quantity of the liquid to flow out

It has been contended that a strange foreshadowing of the X-rays is to be found in a book by Dr. Andrew Blair, entitled "Annals of the Twenty ninth Century." The date of the work is not given, but the prediction, if it may be called such, runs as follows

"I perceived the Secundines could not only make glass and stones and all inorganic substances malleable, but possessed a power unrevealed by man of making them transparent. I was shown animals upon which the youths were taught zoo ogy and comparative anatomy, in some of which the skin was like a glass case showing beneath the working of the muscles In others the skin and muscles were pellucid, showing the circulatory system In others all was pellucid save the bones, with the view of their being subservient to the study of osteology."

When the X-rays were first detected by Prof Rontgen by their action upon a fluorescent screen and upon a photographic dry plate, the newspaper scribes gave the discovery the erroneous title "the new photography," quite ignorant of the fact that the dry plate was no more than a recorder of the phenomenon Strangely enough, what we may call the "old photography," by which is meant the usual process with camera and lens, was the subject of prophecy many years ago. This is perhaps not so remarkable as the instances of prediction already given; for although the invention of the *camera obscura* is commonly attributed to Baptista Porta in the sixteenth century, its principle was well understood many hundred years before his time. And we may feel confident that many must have dreamed of the possibility of making the images formed by the sun take a more permanent form. Especially would this be the case after Scheele, the Swedish chemist, had shown in the eighteenth century that silver chloride would darken under the action of light. La Fontaine, who died long before Scheele was born, gives in one of his fables a method of picture-making which may be regarded as foreshadowing the beautiful art that is now of service to mankind in so many different ways. It occurs under the title "Voyage Supposé," and a description runs as follows:

The Scientific American had two subscribers in a small town in which I lived 30 years ago.



My father was postmaster and I was able to know the number of general publications coming through the mails. I was especially interested in this information because I was business manager of a daily and weekly newspaper published in the same city.

In developing our printing business I was confronted with buying an electric motor. I had no way of determining what I ought to have and consulted with the two men who in that locality had the reputation of being authorities on mechanical matters

It may have been a coincidence, but I prefer to believe it was a logical sequence that the two men who were generally consulted in the purchase of new machinery by city and county officials and by citizens generally were the two subscribers to the Scientific American.

As I spent several thousand dollars on their advice, I can truthfully bear testimony to the influence of the Scientific American beyond the direct contact with its subscribers.

It is a matter of conviction with me when I urge manufacturers of all kinds of mechanical devices to advertise regularly on annual contracts in the Scientific American.

"There was no painter in that country; but if anybody wished to have the portrait of a friend, of a picture, a beautiful landscape, or of any other object, water was placed in great basins of gold or silver, and then the object desired to be painted was placed in front of that water. After a while the water froze and became a glass mirror, on which an ineffaceable image remained."

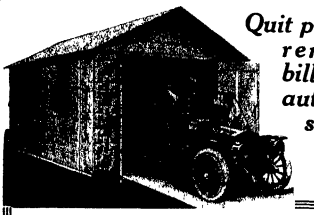
Welding vs. Soldering

By Charles Keyes

IN following the simple law of physics, that a thin piece of metal will melt sooner than a thicker one, we have the solution of welding metals of the same degree of purity In making a ring or band, for example, after approximating the divided ends, place in the joint a piece of the same metal, very much thinner—the thickness or thinness to be decided according to the relative states, the piece usually being about one-eighth or one-twelfth the thickness of the piece to be soldered or welded. The thin piece should be placed in the joint so that it projects on the upper or outer side slightly more than on the inner or under side and also extends beyond the joint all around After the pieces have been properly fluxed, they should be heated—better by a blow-pipe Care should be taken that they be heated all together, not projecting the flame upon the thin piece until the whole is heated almost to melting point

This method is especially useful for dentists in crown and bridge work, and it may also be applied in many arts and industries, such as making brass and wrought iron pipes, etc

In dentistry, for instance, in soldering the cap to the band, in making a crown, if an abutment, use a piece of gold one half the thickness of the band, letting it project around the edge of the band—the circumference being about one-sixth larger than that of the band—then press it down to fit perfectly, having fluxed it beforehand, and follow the edge all the way around with the blow-pipe until it melts



In soldering a cap on an ordinary gold crown, after the band and cap are fitted accurately, place on one side a small piece of, say number sixty, gold foil, flux well, see that its position is correct, then direct the blow-pipe on the piece of projecting foil until the joint is fastened Thus you will have the two parts accurately adjusted and fixed Now take another piece of, say number sixty, foil, large enough to project about one-sixth of its size around the circumference of the crown, cut out a little piece from the center, slip it between the band and crown, cutting out enough to fit accurately around the part attached, flux well, adjust the cap and band, and proceed as in the previous instance. The many applications this may have in jewelry work will be readily understood

In brass, or the noble metals, the procedure is much the same In welding iron, the process is very similar also. For instance, in mending a cracked cast iron cylinder, saw the crack, or file it, to its full extent, making the crack not too wide, then fit accurately a clean piece of thin wrought iron sheet in the joint, allowing it to project beyond all the extent of the crack in the same proportion as in the gold work Heat well, and with the arc melt it to its place

From the above one may see the many uses this method may have, each industry working out its own application

Starch Without Photosynthesis

PLANTS containing the green coloring matter characteristic of grass and leaves obtain their carbon food by the process of decomposing the carbon-dioxide of the air and recombining the carbon with the elements of water into sugars and starches It has been supposed that all starch is a product of this photosynthetic process. L. Caillatet reported to the Academy of Science of Paris the results of some experiments which would indicate that green plants are capable of utilizing as a source of carbon the remains of plant and animal tissues usually found in the soil. His experiments were conducted with ferns of the genus *Adiantum* and consisted in growing specimens in clean quarts sand

Quit paying garage rent or storage bills. Have your auto handy and safe in a fire-proof garage of your own.

Here is a garage, as strong, durable and handsome as masonry and even greater in its protection—but *costs only one-third to one-half as much*

THE PRUDEN GARAGE is the *only* portable garage that is *absolutely proof* against fire—also against damp, lightning, storm or vandalism It is no flimsy, wooden frame affair, covered with sheet iron or canvas *Not a piece of wood in it*—but entirely made of heavy galvanized steel Won't rust or corrode. As substantial as granite. Lasts a life time, yet can be set up or taken down at your will You can put up the Pruden Garage yourself in a few hours, without previous experience. The

PRUDEN SYSTEM OF PORTABLE FIRE-Proof CONSTRUCTION

Makes this easy. The units are machine fashioned and fit together closely and accurately. Our plans and instructions make erection simple.

Between Pruden and other portable garages, there is no comparison—if you care for real protection. If your car is worth protecting at all it is worth Pruden protection. Almost every day the papers report the burning of garages and the loss of autos. A gentleman in Winnipeg recently lost his Winton while a Pruden Garage was on its way to him Don't take any chances of loss The money you put into rent, and garage bills, will in a year or two pay the cost of a Pruden Fireproof Garage and absolute safety.

Mail Coupon for Catalog Today—

Be sure to give name and model number of your car. We can then write you fully as to the size and style of Pruden Garage we recommend for your use All Pruden Garages are rigidly guaranteed Mail the Coupon to today

The Good Road For Universal Service!

Every man's home faces on a road which connects with every other road and leads to every other home throughout the whole land.

Main highways connect with cross-roads so that a man can go where he chooses easily and comfortably if conditions are favorable. But the going is not always the same; some roads are good—some are bad.

The experts in the South illustrate the difference by showing four mules drawing two bales of cotton slowly over a poor, muddy cross-road, and two mules drawing eight bales of cotton rapidly over a first-class macadam highway.

The Bell Telephone lines are the roads over which the speech of the nation passes.

The highways and by-ways of personal communication are the 12,000,000 miles of wire connecting 6,000,000 telephones in homes on these highways. Steadily the lines are being extended to every man's home.

The public demands that all the roads of talk shall be good roads. It is not enough to have a system that is universal; there must be macadamized highways for talk all the way to every man's home. A single section of bad telephone line is enough to block communication or confine it to the immediate locality.

Good going on the telephone lines is only possible with one policy and one system. Good going everywhere, at all times, is the aim of the Bell system.

AMERICAN TELEPHONE AND TELEGRAPH COMPANY
AND ASSOCIATED COMPANIES

One Policy *One System* *Universal Service*

The reason why—

the Scientific American holds its old readers and is gaining in circulation so rapidly is that it is *interesting*. We recently asked our subscribers to send us the names of people whom *they* believed the Scientific American would interest and the "interestingness" of the magazine is demonstrated by the large number of the names so received which have been added to our regular subscription list. Have you sent us a list? If not

Here is the way:

Simply send us the names and addresses of the people whom you think will be interested and we will do the rest. An accurate record of all names received in this manner is kept, and for each new subscription got from any list we extend the subscription of the person who sent us the list for four months. Thus if we receive three new subscriptions from any one list the subscription of the person who sent us the list will be extended for a full year.

Of course you may send as many names as you wish, the greater the number of names you send the larger the number of subscriptions we will probably receive and the longer the period for which your own subscription will be renewed.

Be careful to write the names and addresses plainly and don't fail to put your own name and the address at which you are receiving the Scientific American on each list you send.

Address all lists to the Circulation Department, Scientific American, 361 Broadway, New York.

and others in normal soil. He found that the fern could utilize now the carbon of the air and at other times the carbon of the soil or both simultaneously. The variation seemed to depend chiefly on the intensity of the illumination. Specimens in the sand supplied with suitable inorganic food and water did not grow under conditions of lighting identical with those that normally obtain in the plant's natural habitat; under the same conditions the specimens in soil containing organic debris grew very rapidly With stronger illumination there is more dependence upon atmospheric carbon.

Influence of Manganese on Fermentation

At a recent meeting of the Academy of Science of Paris, E. Kayser reported some interesting experiments with extracts of beer yeast. He had previously found that the presence of manganese salts exercised a favorable action upon the alcoholic fermentation of brewer's yeast increasing the yield of alcohol. He has now tried similar experiments with the juices of the yeast obtained by drying, pulverizing and extracting. He used phosphates and nitrates of manganese and potassium in comparative fermentations and found constant differences in favor of the manganese.

Important factors in determining the activity of the extract are the temperature of the maceration and the condition of the yeast at the time of drying For example, yeast that had been allowed to stand for some time gave juices of variable activity; the best results were obtained from yeasts that had stood from 35 to 40 hours in about 77 deg F Such yeasts macerated in three parts of water gave juices which, when mixed after filtering with 60 per cent of their weight of sugar, liberated gas within five minutes.

A Scientist's "Who's Who"

THE need of a book of reference containing the names, appointments and achievements of the world's foremost scientists has long been felt in learned circles. Messrs J & A. Churchill have in preparation a new annual which is designed to meet this want. It will be called "Who's Who in Science" and is to be edited by Mr H. H. Stephenson.

Schedules are now being addressed to the scientists whose names may appear, and it is hoped that they will assist the publication by filling in and returning the forms to 7, Great Marlborough Street, London, W., as soon as possible.

For enabling scientists to communicate with each other all the world over, and for giving a rapid summary of the achievements and careers of great men the new annual should prove itself indispensable.

Writing to the publishers, Sir E Ray Lankester, K. C B, F. R. S., says: "I feel sure that your new publication will be a great convenience to all who are engaged in scientific work and in literature connected with it. I wish you every success in this new enterprise."

Variations of Alpine Glaciers

THE curves of variation of glaciers which are collected in the Alpine Museum in Berne show, according to Prof. Brueckner, that the 26 great glaciers of Switzerland which were very extensive at the beginning of the 19th century, thereafter receded at first slowly and then more rapidly, until the close of the century. The course of recession was interrupted, about the middle of the century, by a brief advance, in which only two glaciers exceeded the limits that bounded them at the commencement of the century. The glaciers showed a second slight advance between 1890 and 1895.

Although the curves of the various glaciers are similar in general, each exhibits well marked peculiarities, which make it difficult to trace any connection between climatic changes and fluctuations in glaciation. The problem of the glaciers is still involved in obscurity and much patient research will be required to effect its solution.

Science

Detecting Fire Damp by Miners' Safety Lamps.—At the recent soirée of the Royal Society, Sir Henry Cunynghame and Prof. Cadman exhibited a contrivance fitted to miners' safety lamps for the detection of fire damp. The contrivance consists of a small piece of asbestos soaked in carbonate of soda, which can, at will, be introduced into the flame of the lamp without the necessity of lowering it. The presence of small percentages of gas is immediately indicated by the appearance of an orange-colored cap of the same character as appears when a wire, charged with soda, is introduced into a Bunsen gas flame.

Life-rings on a Mountain.—An extraordinary example of the way in which a mountain may afford on a small scale an image of the earth's climates, arranged in successively higher circles, has been found in the San Francisco peaks. These ancient volcanoes rise out of a plateau having a mean elevation of 7,000 feet above sea level. The peaks are encircled with zones of vegetation, which run almost like contour lines around them. Between 6,500 and 8,500 feet the yellow pine is the dominant tree. From 8,500 to 10,300 feet the Douglas fir, the silver fir, the cork fir, and the aspen share the available ground. Between 10,300 and 11,500 feet the Engelmann spruce and the fox-tail pine take possession, and ascend to the tree limit.

Radium in Medicine.—According to experiments made by Prof. Danne, of Mme. Curie's laboratory, and other scientists, radium can be introduced into the tissues by what resembles an electrolytic method. Rabbits and cows, also persons, were operated on, and the radium passed into the tissues without injury to the skin. The penetration is independent of the blood circulation and goes in to some depth, and the effect lasts for quite a time, so that cures can be made in this way. Some of the curative effects of the radium were quite remarkable, as was brought out by Dr. Haret at a recent meeting of the Academie des Sciences.

Vulcanological Studies in Naples.—The Italian government has appointed Prof Giuseppe Mercalli director of the Vesuvius Observatory, and has granted him the sum of $10,000 to rehabilitate the equipment of that institution. At the death of Prof. Matteucci, the late director, it was found that the *matériel* of the observatory had fallen into a deplorable state of inefficiency; hardly an instrument was in working order. The importance of this institution is likely to be overshadowed shortly by the establishment in Naples of an International Institute of Vulcanology. This project, which was originated by Dr Immanuel Friedländer, and which had the hearty indorsement of the recent international geological congress at Stockholm, contemplates an original outlay of $300,000, and an annual expense of $10,000 A good start has been made toward securing the necessary subscriptions.

The International Congress of Applied Chemistry.—President Taft has appointed the official representatives of the government on the organizing committee of the International Congress of Applied Chemistry. The representative from the Patent Office is Dr. George S. Ely of the chemical division The Eighth International Congress of Applied Chemistry will hold its opening meeting in Washington September 4th, 1912, and other meetings, business and scientific, will be held in New York beginning Friday, September 6th, 1912, and ending Friday, September 13th, 1912. The Congress will meet in the United States in response to an invitation extended by the President by authority of a joint resolution of Congress on March 4th, 1909, at the instance of the representation of more than four thousand American chemists, the invitation being extended to the Seventh International Congress in London June 2nd, 1909, by the Hon. Whitelaw Reid, ambassador. The official representatives appointed by the President includes also Dr. H. W. Wiley of the Bureau of Chemistry; Dr. C. F. Langworthy of the Office of Experiment Stations of the Agricultural Department, and many well-known scientists of the country.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are shown the articles stand and the facts entitle the contributions will receive special attention. Accepted articles will be paid for at regular space rate.

The purpose of this journal is to record accurately and in simple terms, the world's progress in scientific knowledge and industrial achievement. It seeks to present this information in a form so readable and readily understood, as to set forth and emphasize the inherent charm and fascination of science.

An Imminent Railroad Danger

WE are so much accustomed to speak of the perfection of the track and equipment of our leading railroads that the occurrence of such a disaster as happened last week at Bridgeport to the Washington express fills us with dismay and raises a very grave doubt as to whether we have even yet discovered how to make the modern high-speed train a perfectly safe means of travel.

Broadly speaking, railroad accidents are due to failure of either the physical or the human element—the roadbed and rolling stock or the operating employee. The Bridgeport accident, according to the statement given out by the officials of the road, was due immediately to the failure of the engineer in charge of the train, remotely, however, it must be regarded as due to track conditions, which, had they been other than they were, would have prevented the accident in spite of the carelessness of the employee.

The line of the New Haven Railroad at the scene of the accident is a four-track road, the outer tracks of which are mainly reserved for local or suburban service, and the two inside tracks for express service. At the stations the express trains, unless express platforms are provided, make use of the local platforms, crossing over for this purpose from the express to the local tracks at a point some distance back from the station. It is customary for the expresses to slow down on approaching the switch of the cross-over, and it seems that, in the case in question, the rules of the New Haven road call for a reduction of speed to fifteen miles an hour. The officials of the road have stated that the engineer ran his heavy express train over the switch at a speed that was nearly sixty miles an hour.

Now, at any such speed as this, the inertia of the engine was too great for the flanges of the wheels to do their work effectively in holding the train on the track. It mounted the rails and plunged down the embankment, with the result that some fourteen people were killed and half a hundred wounded.

Unquestionably in this day of high-class track and rolling stock the most prolific source of accidents on railroads is the failure of the human element. For some reason which will never be explained, since the man is dead, the engineer either failed to observe or to obey both the signals and the speed regulation. It was hot weather and he had gone through a heavy day's work—possibly he was in a state of physical weariness which caused a temporary mental lapse. Whatever the explanation, the fact remains that we have here one more railroad disaster attributable to human failure, and the question immediately presents itself, "Would it not be possible to arrange this matter of cross-overs or turn-outs for fast trains, so that the safety of the train would be automatically taken care of, and not be left dependent on the mental and physical condition of the engineer?"

The answer to this question is that it would be entirely possible, in the great majority of cases, to so construct these cross-overs that even if regulations as to slow running were overlooked or disobeyed, an express train would run through from one track to the other without any serious risk of derailment. This could be done by making the cross-over extend over a greater distance, measured along the axis of the roadbed, and making the angle of the frogs, switches, etc., as small as is compatible with structural requirements. It would be entirely possible to lay out the track with switches and curves so easy that if a heavy express train disobeyed its orders (say for a 30-mile speed at the cross-over), and swept over it at a speed of 60 miles an hour, it could do so without any grave risk of derailment.

Now we understand that at least one of our leading railroads has already adopted this plan. Its cross-overs are so gradual and the length of the cross-over between switches is so great, that the trains are swung from one track to the other, even when they are running at high speed, at the will of the signal man, and without the imposition of any speed reduction upon the engineer. These are the ideal conditions; for construction of this character eliminates entirely a risk of operation, whose magnitude is only appreciated in the presence of such a frightful disaster as that which recently occurred near Bridgeport.

We commend this most important subject to the joint consideration of the Interstate Railroad Commission, and of the maintenance of way engineers of our railroads. The lengthening out of cross-overs would be one more step in the elimination of the human element as a predisposing cause for accidents, and therefore it would be consistent with the policy which has brought about the introduction of the automatic block signal system and similar safety appliances for the protection of life in railroad travel.

Causes of Aviation Accidents

ACCORDING to the conclusions of Lieut.-Col. Bouttieaux, who has just prepared a careful report upon the principal causes of serious aviation accidents, these may be divided into four classes, due respectively to faults of construction, mistakes of the pilot, state of the weather, and finally, either to the fault of the public or to one of a variety of special or ill-determined factors.

Up to the first of the present year, there is a record of 31 fatal accidents, costing the lives of 84 persons. Of these, twice as many took place in 1910 as in 1909, but if we take into account the fact that the number of aviators had been quintupled, the proportion descends to 40 per cent of the previous year. Seventeen of these accidents were due to bad construction, 2 to atmospheric perturbations, 9 to faults of the pilot, and 3 to other causes.

The classification of *simple* accidents, i. e., those without tragic results, gives in the above-mentioned classes the figures 26, 27, 33, and 81. Hence, in the total, 29 per cent of these accidents are imputable to the construction and 27 to the piloting of the machines.

The following summary of the accidents per year is illuminating: First, imperfect construction was responsible for 14 accidents, 1 of which was fatal, in 1909, and in 1910, for 29 accidents, 16 of which were fatal. Second, errors of pilot caused 21 accidents (1 fatal) in 1909, and 21 accidents in 1910, of which 8 were fatal. Third, atmospheric disturbances caused 4 accidents (none fatal) in 1909, and 25 (2 fatal) in 1910. Fourth, imprudences of spectators or aviators and other special or ill-determined causes were responsible for 8 accidents (1 fatal), in 1909, and for 26 accidents in 1910, of which 2 were fatal. The total number of accidents in 1909 was 47, and in 1910 there were 101 accidents.

The increase of accidents due to atmospheric conditions is explained largely by the fact that in 1909 aviators dared not risk their lives in all sorts of weather, as they began to do later, while the greatly increased number of aviation meets had as a corollary an increase in the number of accidents of class 4, caused by faults of spectators or collisions in a restricted landing place.

Faults of construction may be divided into those which may be ascribed to the principle of the machine, and those due to imperfect execution of a plan theoretically perfect. The proportion of the first to the second is as 2 to 43, which does honor to the conception of the aeroplane.

Among accidents of construction, those involving the wings amount to 18, and they frequently were due to a rupture at the line of union with the fuselage, especially in monoplanes. The results are among the most terrible, with 11 cases fatal, and the others very serious. Those ascribable to the motor or controls were 17 in number, of which 5 were fatal. The propeller entered into 6 accidents, in 5 of which it was of metal.

Errors of pilotage brought about 42 accidents, of which 9 were fatal. Among these, faulty turns entered into 24, of which 3 were fatal, while the manner of landing occasioned 8, of which 5 were fatal.

Too sudden an ascent, causing a loss of sustaining power to the machine, in consequence of the insufficient power of the motor, caused 9 accidents, with 1 fatality.

Of reciprocal injuries between aviators, 5 resulted from too close a proximity of passage and the resulting air "wash."

There is nothing to show whether biplane or monoplane is the more subject to accidents, for if more fell to the share of the former, that is due, for the moment at least, to the circumstance of their majority; the percentage was about the same.

How may these causes of accident be overcome? The author of the report advises, in the first place, the use by pilots of helmets, belts, and other safety devices in the shape of garments, which will be efficacious in cases of moderate fall. For machines he recommends shock absorbers and especially a lightly-constructed prow, the breaking of which would serve to deaden the shock. It would, in fact, be desirable that special experiments should be made with reference to the localization of a weak point upon which the initial effect of a shock would be expended, just as in every electric circuit a fuse is introduced at some point where will be localized the effects of a chance excess of voltage.

As for parachutes, their tests have thus far been too few to be commented upon.

Dangers from faulty construction may be minimized by demanding a certificate of navigability and enforcing certain requirements of construction with reference to the choice of materials and the strengthening of the controls.

For the pilot the addition of automatic stabilizing apparatus would be desirable; but these must be practical and efficacious, which is at present only a hope. Equally useful would be instruments indicating loss of speed, exaggerated incidence, lateral sliding toward the center in turning, etc.

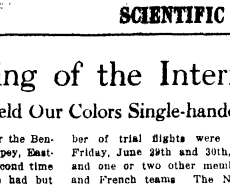
The education of the pilot, improving progressively, on his part, will tend to eliminate risks of aviation, while greater difficulty in obtaining a pilot's license will, to some extent, limit accidents to the period of apprenticeship. Casualties due to meteorological conditions are more difficult to avoid, if not impossible. The best remedy would be a deeper knowledge of meteorology and topography, and the making of appropriate topographical maps will contribute to this end. The education of crowds, as well as fewer aviation meets, will diminish the risks occasioned by them.

The conclusions of the report are very encouraging. Bouttieaux proves that the increase of accidents, so alarming at the first view, arises from the great progress made by aviation, and this in spite of the indisputably rudimentary character of several of the machines. The improvement of these, whose era is just dawning, will render them steadily safer and more manageable, till a reasonable degree of safety is assured.

The Albedo of Clouds

THE albedo of clouds varies between wide limits, but was formerly assumed to average about 0.75; i. e., the upper surface of the clouds was supposed to reflect about 75 per cent of the incident sunlight. The albedo of white paper is 0.70; of new-fallen snow 0.78. The first attempts to measure accurately the albedo of a layer of clouds seen beneath an observer posted on the top of a mountain were those made by Abbot and Fowle on Mount Wilson in 1906, and gave an average of 0.65, but this result was later found to be doubtful, owing to errors in reduction. Within the past few months this problem, which has such important bearings upon the physics of the earth's atmosphere, has been taken up in Germany by Messrs. Stuchtey and Wegener, who made numerous measurements with a specially constructed albedometer in the course of several balloon voyages. They found the following values, which have been corrected by eliminating the general radiation of the sky, and refer only to the proportion of direct sunlight reflected: Lower stratus clouds, 0.54; higher stratus, 0.76; cumulus, 0.67. They also measured the albedo of the earth's surface as seen from altitudes between 600 and 1,650 meters. The albedo of open fields was found to average 0.15; of woods, 0.06.

The Winning of the International Aviation Trophy



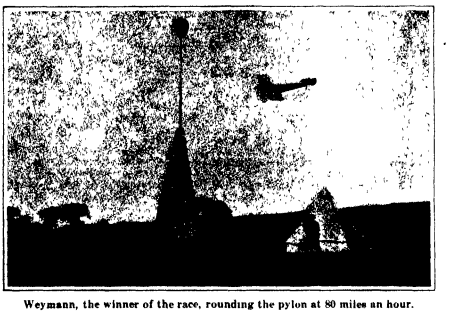
How Weymann Upheld Our Colors Single-handed and Won the World's Greatest Speed Event

THE third international aeroplane race for the Bennett trophy was held at the Isle of Sheppey, Eastchurch, England, on July 1st, and for the second time America came out victorious, although she had but one representative against the three each of France and England. After attempting to get the Wrights and Glenn H. Curtiss to represent America this year in the race, the Aero Club officials finally secured Charles T. Weymann, the young aviator who has made a name for himself in aviation abroad, to endeavor to bring back the cup to America. It was first won in 1909 by Glenn Curtiss, who went to France with his own machine and beat Blériot with his fast monoplane. Last October, at Belmont Park, Grahame-White won the race on account of an accident to Leblanc, Blériot's chief pilot. The Englishman won on a Blériot monoplane, as there was no rule requiring the machine to be built in the country which it represented. The Nieuport monoplane, during the past six months, has proved itself to be one of the fastest and one of the most efficient aeroplanes; and as there was no rule forbidding it, Mr. Weymann decided to use one of these machines, which he has flown considerably of late. He was obliged to abandon the Paris-London-Paris circuit race, in which he was among the leaders, at Utrecht, in order to fly in the cup race; but the result of the race amply justified him in doing this.

For the past eight or nine months M. Blériot has been experimenting upon speed machines. Several months ago we gave information about his latest speed monoplane, which had a peculiar shape of wing and was fitted with a powerful motor. Blériot experimented with a 140-horse-power 14-cylinder Gnome motor, and it was thought that the machine for the race would be equipped with one of these engines, as well as with the peculiar shape of wing, with flexible rear edge, with which he had had his greatest success. When M. Leblanc appeared at Eastchurch with a machine having wings of only one meter width and a total spread of nine meters, or, in other words, nine square meters (96.876 square feet) surface, and fitted with a 100-horse-power Gnome motor only, he sprang a surprise upon aviation enthusiasts, who doubted whether he could win the race with such a diminutive machine, equipped with no more powerful motor than he used last year. The Nieuport monoplanes, however, had only 70-horse-power motors, and consid erably larger wings. One of them, driven by Chevalier (who was the third man on the French team), had only a 50-horse-power Nieuport motor. Nieuport himself drove a 70-horse power Gnome-engined machine, as did also Charles T. Weymann.

The English team was made up of G. Hamel on a 100-hörse-power Blériot, which was practically a duplicate of Leblanc's; Alec Ogilvie, on a baby Wright fitted with a 50-horse-power N. E. C. two-cycle motor; and Graham Gilmour, on a Bristol monoplane. As reserves, England had Messrs. J. Radley, J. Valentine, and O. C. Morrison. Mr. Radley flew in the Bennett race last year, as did also Mr. Ogilvie. The latter completed the race last year on a Wright biplane, and secured third place. This year he used an English-built Wright machine constructed under the supervision of Wilbur Wright, and fitted with a four-cylinder V-type two-cycle motor, recently illustrated in our columns.

The reserve members of the French team consisted of Aubrun, who flies a Deperdussin monoplane; Vedrines, the Morane pilot; and Gibert, with his R. E. P. The Frenchmen had on hand at the time of the race four extra Nieuport monoplanes, three Blériots, two Deperdussins, and one R. E. P. A number of trial flights were made on Thursday and Friday, June 29th and 30th, by Weymann, Nieuport, and one or two other members of both the English and French teams. The Nieuport monoplane was booked as the winner, and it was thought that Weymann stood an excellent chance. July 1st dawned clear and pleasant, although there was considerable wind in the morning and early afternoon. The race was scheduled to start eight hours before sundown, but the flying did not begin until about 3 P. M., at which time the wind was blowing at less than twenty miles an hour. The course was six kilometers (3.72 miles) in circumference, and was over level, smooth ground. Its only disadvantage was its proximity to the sea, which, of course, was responsible for the rather stiff breeze that blew some of the time.



Oglivie rounding the pylon on his baby Wright racer.

Note the sharp angle at which the aviator is ascending. This is to allow for dropping of the machine in making a turn.

Leblanc doing 75 miles an hour on the straightaway.

Note the narrow wings and the finely tapering lines of the body of his high-powered machine.

Weymann, the winner of the race, rounding the pylon at 80 miles an hour.

The fuselage shape of the body (which is entirely covered with cloth) is well shown in this picture. It is to this form that the greatly diminished head resistance is largely due.

Wreck of Hamel's Blériot. The aviator escaped uninjured.

The 14-cylinder, 100-horse-power Gnome motor is clearly seen, as is also the specially tapered fuselage used on this racing monoplane.

SCENES AT THE GREAT RACE.

Gustave Hamel, the English aviator, was the first to start, which he did at 4 P. M. It was thought that he would do well, as he had made an excellent showing in the morning while practising. Instead, he banked too much on making the turn on his first round of the course and his machine slid sideways to the ground, and was smashed to pieces. The aviator luckily escaped without any serious injuries. Shortly after Hamel's accident, Weymann started in his Nieuport monoplane. He rose to the height of 100 yards or so, which elevation he maintained through out the entire twenty-five circuits of the course. He covered the first five circuits (30 kilometers) in 14 00 2/5. Chevalier was the first Frenchman to start. He flew fairly well in his low-powered Nieuport, but alighted after completing ten laps, and did not finish the race.

As Gilmour withdrew, England's only remaining representative was Ogilvie, who flew his baby Wright in excellent fashion, though he was unable to make anything like the speed of the Nieuport or Blériot monoplane. Nieuport covered the first five circuits in 14 46, whereas Ogilvie required 21 45 to fly the same distance (18 miles). Leblanc was the last to ascend. He covered the first circuit in practically the same time as Nieuport, and at the end of ten laps, which he covered in 29 29 4/5 he was only four seconds ahead. He was still ahead of his compatriot at the end of fifteen laps, and although he succeeded in the end in beating the latter by 57 seconds, he failed to beat Weymann by 2 minutes 24/5 seconds.

The time of the winner in the race was one hour, eleven minutes, thirty-six and one-fifth seconds, which corresponds to an average speed of 78.1 miles an hour. Leblanc was second in 1 12 40 1/5—an average speed of 77.91 miles an hour. The third place went to Nieuport in 1 14 37 3/5 (74.94 miles an hour), and fourth to Ogilvie, in 1 49 10 2/5 (71.22 miles an hour). Chevalier's time for his ten laps was 37 37 1/5. This corresponds to an average speed of 59.3 miles an hour, which is very good, considering the low power of his machine.

The winning of the race by America should serve to stimulate aviation in this country greatly, especially since next year the rules will probably be changed so that the machine and pilot must both be the production of the country which they represent. As speed is the desideratum of the racing aeroplane, and the thing for which it exists, we believe that if our inventors can develop the speediest and at the same time the safest, flying machines they will again cause America to lead the world in aviation, just as she did at the start.

South Sea Swells

WE all remember with what frequency in the old narratives of experiences in the South Seas reference is made to the heavy swells of the ocean which impressed the navigators with the idea of their remoteness from land.

The great size of the sea waves in high Southern latitudes has been explained by the fact that south of the Cape of Good Hope and Cape Horn there is neither windward nor leeward shore, and the prevailing wind in all longitudes is westerly. Thus when a west wind springs up it finds a long westerly swell, the effect of a previous wind, still running. The new-born wind increases the steepness of this swell, and so forms majestic storm waves which sometimes attain a length of 1,200 feet from crest to crest. The average height attained by sea waves in feet is about half the velocity of the wind in miles per hour.

The Beacon Hill Tunnel

How a Half-mile of the Boston Subway Was Built in Tunnel

By G. D. Emerson

THE most recent underground construction in the Boston district for the use of street railway traffic is the tunnel through Beacon Hill, which is now nearing completion. This tunnel, which is a little less than half a mile in length, does not follow the street lines, but runs through the middle of Beacon Hill in a general northwesterly and southeasterly direction, connecting at its northwesterly end with an elevated structure which will cross the Cambridge bridge over the Charles River, and at its southeasterly end terminates at present in a station beneath Boston Common, under the Park Street station of the Tremont Street subway. The bottom of the tunnel, at the deepest point is about one hundred feet below the top of the hill. This tunnel forms the Boston end of the new subway lines connecting Harvard Square, Cambridge, with the business section of Boston.

Beacon Hill is presumably a glacial formation, and is composed in general of a very hard mixture of blue and yellow clay and sand, together with numerous small stones and a few large boulders. Irregular streaks and pockets of sand, some containing water, were frequently encountered during the progress of the work. No serious difficulty resulted, however, from the ground-water, and this, together with the hardness of the ground, made it unnecessary to do any of the work in compressed air, although there was a provision in the contract for the work for doing so in case of necessity. At one point, about sixty-five or seventy feet below the surface, some worn fragments of clam shells were found imbedded in the hard blue clay.

The general method of tunneling adopted for this work was by means of a roof-shield, which is quite similar in character to the shields used in the tunnels already constructed in this vicinity. The Tremont Street tunnel of the original subway, the East Boston tunnel and the Dana Hill tunnel of the Cambridge subway.

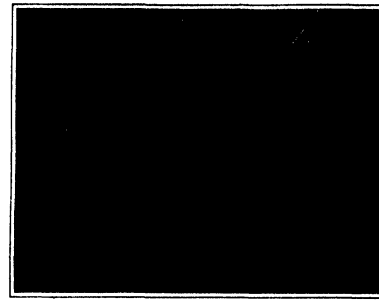
This roof shield is essentially a semi-circular steel frame weighing about sixty-five tons, the diameter of which is equal to the outside width of the tunnel, which is thirty-two feet four inches. Its function is to support the earth above the roof of the tunnel temporarily while the permanent concrete tunnel arch is being built below.

The first operation in this method of tunneling is to dig two small pilot-tunnels—or so-called side-wall drifts. These drifts are about nine feet square, the roof and sides being timbered and they are located at the bottom outside corners of the tunnel section. As fast as they are excavated, the lower part of the concrete side wall of the tunnel is built in them. They are kept from one hundred and fifty to two hundred feet in advance of the shield, so that the concrete walls will have sufficient time to harden before the weight of the shield comes on them. The shield, which rests on cast-iron rollers is pushed along on top of these concrete side-walls by means of hydraulic jacks.

The successive operations are as follows: The earth is excavated for two and one-half feet ahead of the shield, which is then shoved forward through this distance by means of the hydraulic jacks before mentioned. A section of the concrete arch two and one half feet long is then built under the overhanging steel plates at the rear of the shield. The soft concrete is placed on temporary steel centers or supports, which are removed after it has become sufficiently strong. The overhanging plates at the rear of the shield are about one and a quarter inches thick, and when the shield is shoved forward it leaves an annular space of that thickness between the concrete arch and the earth. This space is filled as soon as practicable by pumping in liquid cement grout. In actual work, the operations of excavating ahead and putting in concrete at the rear of the shield are carried on simultaneously. This cycle, which takes about five or six hours, is repeated continuously.

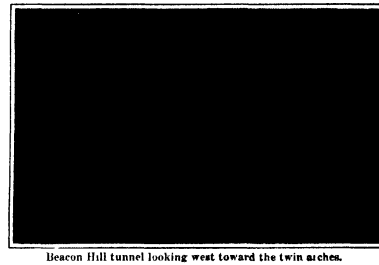
A rear view of the lower part of the shield in actual operation, and showing some of the temporary steel centering immediately behind it, is shown herewith. The upper half of the shield in working condition is also illustrated. As fast as the excavation is completed, and the concrete arch is in place, the concrete bottom is put in.

All machinery for operating the shield and hauling the working-cars in the tunnel is run by compressed air furnished by a compressor plant located near the mouth of the tunnel. As stated above, the shield is shoved ahead by hydraulic jacks, of which there are fourteen, spaced equally around the circumference of the shield. These jacks have plungers eight inches in diameter and work under a maximum pressure of four thousand pounds to the square inch, which gives a maximum pushing force of nearly one hundred tons for each jack, or about one thousand four hundred tons for the whole shield. The jack-cylinders are bolted to the frame-work of the shield and the plungers push against lines of cast-iron rods which are imbedded in the concrete arch. The water, under pressure, for operating the jacks, is furnished by two pumps which are run by compressed air.



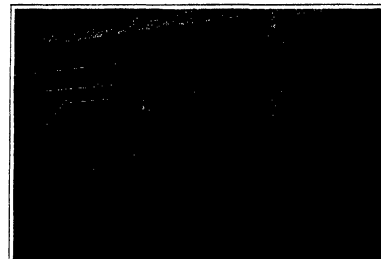
Economy in this kind of construction depends to a large extent upon systematizing and specializing the work. Thus, several different gangs of men do the excavating in the pilot tunnels and on the shield platforms, others put in the concrete walls in the pilot tunnels and the concrete arches at the back of the shield, and still others attend to setting up and taking down the temporary concrete supports, handle the cars which bring in fresh concrete and take out the excavated earth, etc. Each of the different operations is repeated continuously so that by proper systematizing the labor becomes very efficient. Most of the work was carried on by two ten-hour shifts per day, the number of men in each shift averaging about one hundred and thirty. The average progress per twenty-four hours was seven and a half feet, and the maximum progress per 24 hours was about nine feet.

The surface of the hill, over the line of the tunnel, is thickly covered with brick buildings from three to six stories in height. The excavation was carried on in such a manner, however, as to avoid any settlement or damage to them.

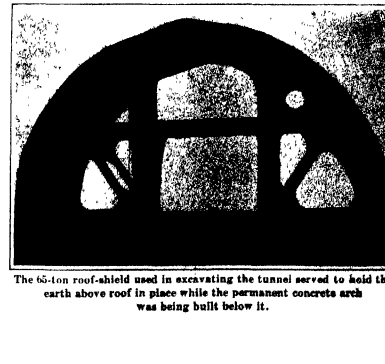


During the course of the work about a dozen old wells that used to furnish the water supply for former residents on Beacon Hill were encountered in the tunnel headings. Some of these old wells were one hundred feet deep and more than a century old, and the hollow pump-logs were still in place, and in fair condition. The first intimation the tunnel workers had of their existence was when the stone lining of the wells fell down into the tunnel when they were reached by the excavations. This resulted in some delays, but no very serious difficulties.

The chief item of interest toward the end of any construction of this sort is where the tunnel "comes out," that is, how close the engineers have been able to run their lines to the theoretical position the tunnel should occupy. Part of this tunnel is on a curve of four-thousand-foot radius, which makes the running of the survey lines somewhat more difficult than if the line were straight. In this particular case the tunnel came out at the final end within less than half an inch of its calculated position.



The Beacon Hill Tunnel is being built for the city of Boston by the Boston Transit Commission, and, upon completion, it will be leased to the Boston Elevated Railway Company.

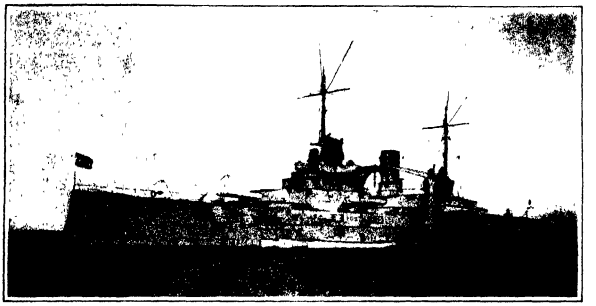


View of steel centers and shield from upper working deck.

Beacon Hill tunnel looking west toward the twin arches.

Rear view of lower part of shield, showing temporary steel centering behind it.

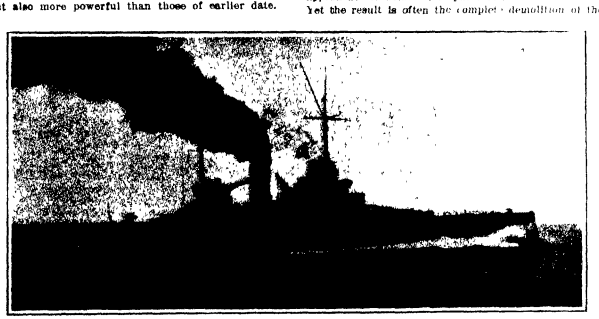
The 65-ton roof-shield used in excavating the tunnel served to hold the earth above roof in place while the permanent concrete arch was being built below it.



A Comparison of the German and American Navies

Our Great Superiority in Gun-fire Places the United States in the Lead.

By H. D. Brandyce



ONE of the most fruitful topics of the day seems to be the phenomenally rapid growth of the German Navy; and the notion is widely held that the Kaiser is adding to his fleet for the purpose of challenging England's age-long supremacy on the sea. Now, whatever may be the Kaiser's idea, such a contingency is not likely to be realized for many years to come, for not only is Germany's naval strength still far inferior to Britain's, but it is at the moment of writing also vastly less than our own.

Until the year 1910 those who made it their business to rank the various fleets of the world had assigned second place to the United States Navy, England holding first position and Germany third, but in the last twelvemonth these critics have seen fit to attribute to Germany a superiority which in our opinion is not borne out by fact. The only fair way to estimate the relative strength of the two navies is to take them ship for ship and compare their respective offensive and defensive qualities. The tonnage method which most naval writers employ is misleading, for it lumps together the armored and unarmored ships, and takes no account of age or design. In this way four unarmored cruisers would equal one battleship and twelve destroyers would rank with one armored cruiser. Obviously the proper means of obtaining relative values is to oppose battleship to battleship, armored cruiser to armored cruiser, as they would presumably line up in actual conflict. And, further, these ships should be as near as possible of equal age, for of course the newer vessels are not only larger but also more powerful than those of earlier date.

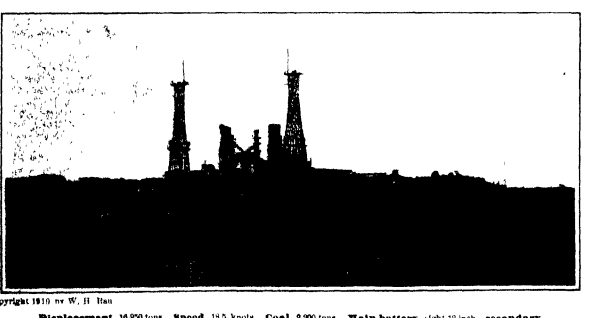
Displacement, 18,900 tons. **Speed,** 20 knots. **Coal,** 2,500 tons; **oil,** 300 tons. **Main battery,** twelve 11-inch; **secondary battery,** twelve 6-inch. **Main belt,** 9½ inches; **upper armor,** 5 inches; **turrets,** 9½ inches.

German Dreadnought "Westfalen."

Displacement, 18,800 tons. **Speed,** 20 knots. **Coal,** 2,700 tons; **oil,** 300 tons. **Main battery,** twelve 11-inch; **secondary battery,** twelve 6-inch. **Main belt,** 9½ inches; **upper armor,** 8 inches; **turrets,** 9½ inches.

German Dreadnought "Nassau."

We need only concern ourselves with four classes of ships—battleships and armored cruisers, destroyers and submarines, for the functions of protected cruisers and gunboat are almost negligible from a military point of view, their activities being properly confined to police duty in time of peace, and, in time of war, to scouting and intelligence service. Of the four classes which we shall consider, the battleship is all-important; it takes its place in the forefront of the line of battle, and bears the brunt of the fighting. The armored cruiser is the heavy cavalry of the sea, and but rarely takes its place where the fire is hottest.



In making comparisons of the ships of these two navies, the dearth of positive information on subjects relating to the efficiency of the personnel of the Kaiser's fleet requires that in all matters dealing with the personal equation the two services be considered on a parity. We know nothing definite of the Germans' proficiency in battle practice or in steaming trials; but we may be quite sure that the thoroughness which is characteristic of their nation has brought these things to a high state of perfection.

But no matter how much they may practise at the targets, they cannot overcome deficiency in materials; inferior guns must give inferior results, for, strange as it may seem, Germany, the home of the Krupps and the Ehrhardts, has at this moment not one gun afloat which can pierce our battleships' side-armor at what we call battle range (8,000 yards)! This is a startling fact, and one which must be of supreme importance in making a fair comparison of the offensive power of the two fleets. In our annual battle practice the battleships commence firing at the targets when they are some 12,500 yards away and their firing time is generally exhausted before they have approached to within 8,000 yards of the canvas screen. Yet the result is often the complete demolition of the target, although the mark is a rectangle less than one-fourth of the area of the broadside of a modern man-of-war.*

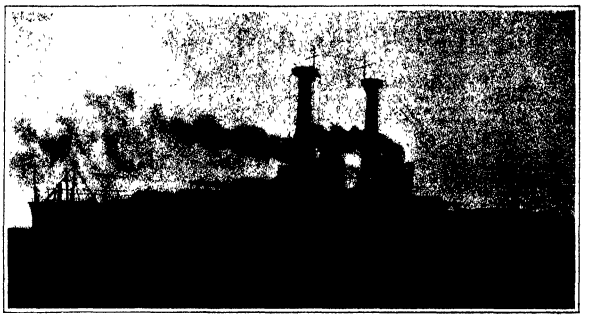
Little or nothing is known about the conditions under which the German High Sea Fleet conducts its shooting, but it is highly probable that their ranges are less than ours, for their lighter guns could not hope to score hits at over 10,000 yards, owing to the fact that the high angles at which they must fire at such great distances would tend quickly to impair the accuracy of their aim. Their new 11-inch guns of 45 caliber† with which, by the way, only their dreadnoughts are equipped—have a very high muzzle-velocity (3,250 foot-seconds), but the relative lightness of the shell (.595 pounds against .850 pounds for our twelves) tends to a rapid falling off in velocity at anything above a point-blank range. So that while at 3,000 yards—which is almost point-blank—their armor-piercing shell will penetrate 22 inches of Krupp armor to 20 inches for our 12-inch A. P. shell, at 8,000 yards the penetrations are 8¼ inches and 11 inches respectively. All this means that in case of actual hostilities between Germany and the United States our vessels in the line of battle could fire with effect at the German battleships at ranges at which the latter could not seriously injure the vitals of our men-of-war. Of course they could do great damage to our upper works and lightly protected ends, but in the meantime—and before they could close in—our heavy artillery would presumably have shot their side-armor to pieces and pounded their turrets until they jammed and were incapacitated for further firing. (At the battle of Tsushima the Japanese sank many of the Russian battleships by long-range firing, the impact of the heavy projectiles against the belt-armor tending to fracture the plates and start the seams so that the water entered in sufficient quantities to flood

* The U. S. armored cruiser "Maryland" won the battleship trophy for 1910 by making 40 per cent of hits with her 8-inch guns at 10,000 yards in a heavy sea.

† The word "caliber" is here used to express the length of the gun in terms of the diameter of the bore: thus a 12-inch gun of 45 calibers would have a length from powder chamber to muzzle of 45 feet.

Copyright 1910 by W. H. Bau

Displacement, 16,050 tons. **Speed,** 18.5 knots. **Coal,** 2,900 tons. **Main battery,** eight 12-inch; **secondary battery,** twenty-two 5-inch. **Main belt,** 12 inches to 10 inches; **upper side,** 10 inches to 8 inches; **turrets,** 12 inches to 9 inches.



United States Dreadnought "Michigan."

the compartments and ultimately cause the ships to turn turtle.)

In the matter of armor protection there is little to choose between the fleets of the two powers when the ships are compared individually according to date of launch. The same holds true of the relative speeds. In coal supply the Americans have a slight advantage as may be seen in the appended tables.

The twenty-six German ships given in the table have a total displacement of 339,220 tons, an average of 13,047 per ship. This *compares* with a *total* for the Americans of 407,650 tons, and an average of 14,057. Let us now examine somewhat more closely into the guns and armor of the later models—say the fourteen most recent Germans and the twenty newest Americans.

Taking first the four "Westfalens." They carry twelve heavy guns each, but these are so arranged that only eight of them can fire on either broadside. The ten heavy guns of the "Delaware," in pairs in five turrets on the center line, can all fire on either broadside which gives the Yankee dread

noughts an immense advantage; and even the relatively small "Michiguns" can oppose the German 11-inch guns with an equal number of 12's. Now at 8,000 yards the 11-inch gun can pierce only 8½ inches of Krupp steel on direct impact, and all the vulnerable parts of the United States ships are covered with from 12 to 8 inches of Krupp armor, and their turrets and barbettes are protected by slanting plates 12 inches thick. Our 12-inch 45-caliber rifle, on the other hand, can send a shell through 11-inch Krupp steel at 8,000 yards, and not one of these four German dreadnoughts mounts a plate more than 9¾ inches in thickness, except on the barbettes. Is it not plain, then, that the four Yankee vessels, with their thirty-six 12's in broadside, are more than a match for the four "Westfalens" and their thirty-two 11's?

The discrepancy between the ten "Hannovers" and the sixteen contemporary battleships of the American navy is even more startling. The German main belts vary from 9 to

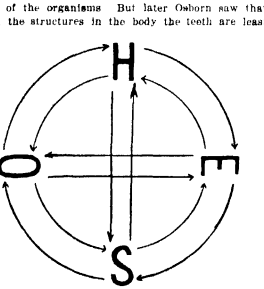
(continued on page 80)

Henry Fairfield Osborn

America's Foremost Palæontologist

By Benjamin C. Gruenberg

TO pursue science because it satisfies the human spirit, without any delusion as to the possible application of his results to the relief of pain or poverty, that is to be a "pure" scientist. Such a scientist is Henry Fairfield Osborn, one of the foremost palæontologists of America. When in 1906 he was tendered the great honor of election as secretary of the Smithsonian Institution, he gave as one reason for declining the post the fact that palæntology was of no immediate use to society and he would, therefore, not feel justified in asking for appropriations to enable him to carry on his costly researches at the probable expense of work more likely to yield results of practical value to the rest of us But he gave as another reason the fact that the material, equipment and assistants necessary for carrying on his researches were located in New York—and with his work he would stay



Prof. Osborn was born at Fairfield, Conn., August 8th, 1857, a descendant of merchants on both sides of the family He received his collegiate education at Princeton, and commenced his career as organizer and manager of scientific research even before he was graduated by organizing and leading the palæontological section of the Princeton scientific expedition to Colorado and Wyoming in 1877 He studied geology under Arnold Guyot, anatomy under Wm H Welch, comparative anatomy under Huxley, and embryology under Balfour While in England he was very much awed and inspired by a casual meeting with Charles Darwin when the latter was visiting Huxley's laboratory He taught natural science at Princeton and studied in Europe until 1881, when he was appointed the first Da Costa professor of biology (after 1895, of zoology) at Columbia University. Here he organized the biology department and established the Columbia University Biological Series, of which he edited the first ten volumes

In 1891 he was also appointed curator of vertebrate palæntology at the American Museum of Natural History During the twenty years of his active administration he brought together a collection of vertebrate fossils that is remarkable not only for being the largest in the world, and for being prepared in the most skillful and instructive manner, but also for the richness of some of its series—that of the horse, for example, being practically complete from early Tertiary times down to living forms of to-day In 1910 he retired from active teaching and administration to devote himself to research

Prof Osborn's contributions to knowledge are chiefly his collection of vast numbers of facts about the structure and distribution in space and time of vertebrate fossils, and his co-ordination of facts of paleontology in relation to the theory of evolution He always insists that palæntology is a branch of biology, not of geology, to which it is joined only through the fortunate accident that fossils are found in the rocks To mistake the position of fossils in the rocks, he says, "as indicative of their scientific affinities, is as logical as it would be to bracket Protozoa, which are principally aquatic organisms, under hydrology, or the Insecta, because of their aërial life, under meteorology" And he accordingly attempts to interpret the facts of palæntology in terms of organic evolution

Among his earlier studies was that on the history of mammalian teeth, which have given the comparative anatomist and evolutionist a great deal of comfort as well as trouble Teeth of primitive mammals, like the teeth of reptiles, have a crown consisting of a simple cone. The complex molars were believed by many odontologists and embryologists to have arisen by a process of "concrescence;" i e, the simple teeth were supposed to have grown together in groups as the jaw-bones gradually became shorter, and formed the compound teeth, just as separate petals were supposed to be "fused together" in such flowers as the cushion or the pumpkin. Osborn, on the basis of mammalian fossils, early came to the conclusion that the complex molars of this class of animals have resulted from the successive addition of cusps to an originally simple tooth which attained a tri-tuberculate form during the Mesozoic period. As a result of further studies he found that with the exception of a few aberrant forms all orders of mammals have shown the tri-tuberculate type of molar teeth, and that the original cone has always been represented by the front cusp on the inner edge in the upper molars, and by the front cusp on the outer edge in the lower molars. He also found that the successively appearing new cusp always followed a definite order. On the one hand, he developed from these studies an exact descriptive nomenclature of the mammalian teeth which replaced the conflicting and confusing terminologies of earlier writers from the time of Owen, and on the other hand, he developed the theory of "determinate variation" in the evolution of organisms

This idea, which he later renamed the doctrine of "rectigradation," he found to be practically identical with the "orthogenesis" of Eimer and other writers, and with the "mutations" of Waagen, and extended it to other structures The cusps of the molar teeth do not appear "fortuitously" and then survive in accordance with their relative fitness, as would be required by the Darwinian theory, nor do they appear fully formed in a discontinuous manner, in the sense of DeVries's theory, they appear at definite points, at first too small to have any adaptive or selective value, and become with succeeding ages larger and larger until they are of adaptive value In other words, they are *determinate* in their origins, they develop *gradually*, and they are *adaptive* in the direction of their development from the very start In his earlier studies Osborn considered these facts favorable to the kinetogenic theory advanced by Ryder and Cope, that is practically the neo-Lamarckian view of the evolution of structures being directed by the habits and needs of the organisms But later Osborn saw that of all the structures in the body the teeth are least

Osborn's modification of Weismann's germ-plasm diagram.

According to Osborn heredity, ontogeny, selection, and environment are inseparable in any discussion of evolution

able to show any such influence because they are fully formed before they emerge from the gums and they cannot improve with use, on the contrary, the more they are used, the more they are worn away, whatever virtues or fitness the teeth of an individual may show are congenital The rectigradations are thus not in themselves the result of selection nor of saltation, neither can they be accounted for on Lamarckian principles, they arise because of some inherent tendency or potentiality to vary in a determinate direction What this internal determining factor is we do not know It is not the same as Nägeli's "internal perfecting principle," since it operates in a direction parallel to ontogeny, that is, it causes evolution to proceed in adaptation to *new external conditions* For example, certain Eocene monkeys had become herbivorous, and their teeth developed so much like the ungulate type that their fossils were at first classed with ungulates

The same principle of hereditary ancestral control of variation was afterward found by Osborn to be illustrated by the origin of horns and other organs, and other workers found parallel facts in various series of fossils The date at which characters develop is determined by external factors, but the nature of the characters is determined by internal factors, at present "unknown" Thus a comparison of Eocene horses with contemporary titanotheres shows that the horse was developing the cusps more rapidly, but both groups were developing the cusp in the same predetermined order the law is illustrated also by the fact that similar characters have arisen simultaneously in groups of animals of common ancestry in Switzerland in Patagonia and in Wyoming On the other hand, certain characters seem to be less firmly bound up with hereditary control An example of this is the shape of the head, which Osborn found in a number of contemporary Mid Eocene branches of titanotheres, of undoubtedly common ancestry, to show a tendency to diverge into narrow and broad-skulled types In each diverging branch, however, once a tendency had established itself, the development proceeded to the limit without reversal

From a study of fossil horses in the course of which Osborn built up the history of this group in a very satisfactory manner, he passed to a thorough study of the titanotheres, which, of all extinct animals furnish the most complete series of fossils Here his earlier generalizations have been amply confirmed, and the "unknown factors of evolution" are still there to be discovered Instead of minimizing the difficulties unearthed by the palæntologists, Osborn thinks that scientific progress can be assured only if we frankly admit the limits of our knowledge in certain directions, he does not say we cannot know, but merely that here we do not know A good summary of his evolution creed was given by him in his address before the Palæntological Section of the International Zoological Congress in 1907

1. Many origins of new characters are due to some internal action in heredity

2 Many important adaptive characters arise determinately, definitely and by extremely slow stages

3 Degrees of similarity in such origins correspond to degrees of kinship

4 Degrees of kinship also affect to a certain extent, but not absolutely, the time of appearance, or the time of the origin, or the rate of evolution

5 The origins find expression not spontaneously, or irrespective of conditions, or from purely internal mechanical causes, but through some entirely unknown and at present inconceivable relation to ontogeny (habit and use) and to selection

6 If such origins do spring from internal hereditary principles, as they appear to do in many cases rapid origins (mutations of DeVries) may be simply due to the same law operating with a different velocity

In all his discussions of evolution Prof Osborn emphasizes the fact that the four recognized factors—heredity, ontogeny, environment and selection—are inseparable, and he criticises much of current debate because now one factor and now another is treated as if it acted uninfluenced by the others He would modify Weismann's well-known diagram showing the continuous line to represent the germ plasm by placing the four factors in a series wherein each is shown as influencing all the others, and being in turn influenced by them His philosophy attempts to harmonize the findings of the experimentalists, of the field naturalists, and of the palæntologists, the last, he says, have the best perspective, for they see the evolution of characters through long ages, without regard to particular organisms or species in which, for the time, they are perhaps being manifested

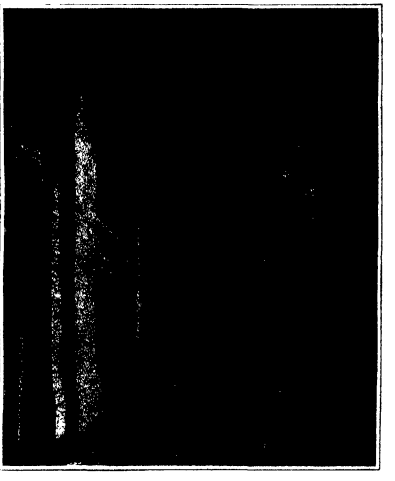
Prof Osborn's career is a splendid refutation of the prevailing clinical conception of "human nature," which can find no incentive to noble endeavor except in the pursuit of material gain guided by self-interest And it also vindicates the "pure" scientist against the charge of impracticality and inefficiency, for every institution with which he has been connected shows the work of a master in efficient organization and administration

Artificial Snails

SNAILS the only genuine part of which are the shells are now being sold in Paris, and it is said that the imitation of the real article is so close that many epicures have a high opinion of the sham product But it is to be presumed that they do not know that the snails are artificial, and they are certainly ignorant of the method by which the snails are manufactured

Snail-shells, it seems, are bought from the dustmen and rag-pickers, and after being cleaned are filled with "lights" or cats' meat, the soft flesh being cut into corkscrew form, so as to fit the shell, by a skillfully designed machine The receptacle is then sealed by means of liquid fat and the escargot is ready for the consumer The secret came out in consequence of an action brought by a man employed at the snail-factory to recover damages for a finger mutilated by one of the machines The artificial snails find a ready market.

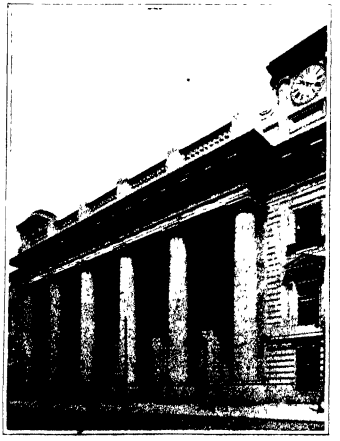
The Latest of the Big Railway Terminals



The Chicago Terminus of a Leading Western System

IN our special railroad number of June 17th last, we gave a description of the largest railroad terminal in the world which is now being built by the New York Central Railroad Company on the site of the old Grand Central station, and we drew attention to the fact that at the present time one of the most marked activities of the big railroads is the great scale upon which they are reconstructing their terminal stations in large cities to accommodate the ever increasing volume of traffic. The present article is devoted to one of the latest and most handsome terminal of this character which has been built by the Chicago & Northwestern Railroad Company as the eastern terminus of their line in Chicago. The station has been built to conform to the general work of track elevation which has been carried out in that city and forms one of its most important modern improvements.

The main shed, 840 feet in length, containing 16 tracks.



The main building of the station is a simple and dignified steel and granite structure four stories in height which has been treated in the early Italian Renaissance style of architecture. The main entrance, on Madison Street, is through a lofty Doric portico, which is carried upon a colonnade of six granite columns, each seven feet in its largest diameter and 61 feet in height. Back of this colonnade is a vaulted vestibule which is 132 feet wide, 22 feet deep and 40 feet high, entrance to the vestibule being by three imposing arches. At each end of the vestibule broad granite stairways lead up to the main waiting room, which is on the track level floor. There are similar vestibules of more simple architectural treatment at the Canal and Clinton Street entrances. These vestibules lead directly to a large public area, 200 feet by 92 feet, around which are ranged the ticket office, baggage room, and other essential accessories. At the center of this public space a grand stairway leads to the main course of the main waiting room on the track floor.

The inner vestibule.

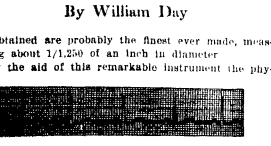
The principal architectural feature of the station is the main waiting room, which is treated as a great Roman atrium, with a barrel-vault roof. The pilasters and the whole order, as high as the spring of the vault, are dull finished in light pink Tennessee marble. The columns are of Greek Cippolino marble, whose delicate green hue harmonizes agreeably with the bronze of the metal work which frames the glass between the pilasters. The vault is of ornamental tile construction, with richly ornamented ribs of terra cotta, whose color harmonizes agreeably with the marble of the walls. Excellent lighting effects are secured by two semi-elliptical windows 60 feet in diameter at each end of the vault, and ten circular lunettes, five on each side. The exterior walls of the station building are of gray Maine granite, and they are made continuous with the walls which inclose the train shed, the latter being of mottled gray brick, with granite trimmings. As the train shed walls rise to a height slightly greater than the roof of the train shed, they assist in giving to the entire station the external appearance of one huge building, and the total effect is enhanced by the dignified front façade, which rises to a height of 120 feet above Madison Street.

Of equal importance to the station building is the train shed, which extends to a total length of 840 feet, and covers in the 16 tracks and 8 platforms which serve the station. The place of the great steel-and-glass arched roof, which formed the invariable covering of large train sheds built from ten to twenty years ago, is taken by what is known as the "Bush roof," this being the first of its kind erected in Chicago. In this type the roof structure is carried on lines of columns, placed down the center of each platform, and the curve of the roof over each pair of tracks is broken by two longitudinal slots, through which the locomotive smoke-stack discharges directly in the open air. The roofs are of steel and concrete, and wired-glass skylights give ample light to every part of the train shed.

The main entrance, portico columns 60 feet in height.

Main waiting room, a dignified classic interior.

THE LATEST OF THE LARGE PASSENGER TERMINALS



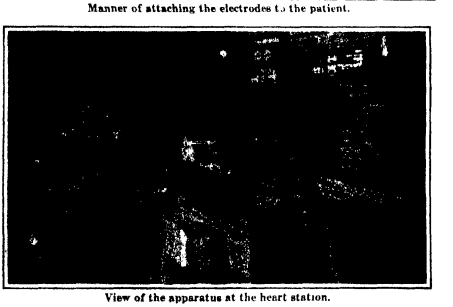
Heart Diagnosis by Electricity

By William Day

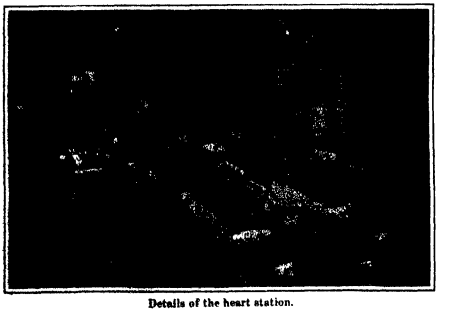
ONE of the most remarkable recent additions to the modern equipment for clinical diagnosis are the so-called "heart stations," now in operation at the Presbyterian and Mt. Sinai hospitals, in New York, and at the Johns Hopkins Hospital in Baltimore. The new apparatus represents the most refined diagnostic instrument at the service of the heart specialist, and not only enables him to follow with great certainty and clearness the specific features upon which his judgment of the case must be based, but it furthermore is capable of yielding data which would be quite unattainable either by the unaided human sense organs or with the aid of the ordinary instruments hitherto employed to extend somewhat the sensibilities of the organs of touch, sight and hearing.

The principle upon which the new method and apparatus are designed consists in the observation of certain electrical currents which accompany and are intimately related to the characteristic phases of the heart's action. The chief credit for the development of this method must be given to Waller, an Englishman, and especially to Einthoven, the noted Dutch physiologist. The latter it is who, in 1903, in his laboratory at Leyden, devised the so-called "string galvanometer," the most essential feature of the new apparatus. In most galvanometers the magnet is the movable part and the current to be measured passes through a stationary coil. In Einthoven's instrument this arrangement has been reversed; the magnet is stationary and the current passes through an extremely fine wire, measuring 0.001 to 0.003 millimeter in thickness. The filament may be of quartz covered with a fine silver coating to render it conducting, or it may consist of platinum. A very serviceable platinum thread would measure 35 millimeters in length, and from 2 to 4 micromes in diameter. This is about one-third to one-half the diameter of a red blood corpuscle. So delicate is the thread that it can be seen with the naked eye only when powerfully illuminated against a dark background. Such a thread is too light to be weighed upon even an extremely sensitive balance. Its weight has, however, been calculated by Einthoven to be about 3 to 7 thousandths of a milligramme. The ends of the thread are fixed, so that the thread is stretched and free to vibrate very much like the string of a musical instrument. This is the feature that has given the name "string galvanometer" to the device. The string is suspended midway between the pole pieces of a magnet, which is preferably an electromagnet. It operates on the principle that when an electric current is passed through a magnetic field, the conductor, if free to move, suffers a deflection perpendicular to the lines of force which pass between the poles of the magnet; thus when a current passes through the string of the Einthoven galvanometer this string is deflected to one side or the other, according to the direction in which the current passes. In order to obtain an accurate indication and record of the oscillations produced by the passage through the galvanometer of the feeble currents originating in the heart, a magnifying and photographically recording apparatus is provided. The cores and poles of the magnet are pierced through their centers, and two microscope tubes are inserted in the openings. One of these tubes is fitted with a lens for focusing a strong electric light upon the string; the other is a projection microscope which throws an enlarged image of the illuminated string upon the slit of the photographing apparatus, or else upon a white screen on which the movements of the thread can be observed directly by eye. Incidentally, it is interesting to note that a filament can be made from quartz fiber by a special process. The threads so obtained are probably the finest ever made, measuring about 1/1,250 of an inch in diameter.

By the aid of this remarkable instrument the physician can see and record the oscillations which the string undergoes as the result of the electric currents generated in the human heart during its muscular excitation which precedes every beat. The rapidity of the string movements, their extent, and the regularity or irregularity of their rhythm reveal significant information regarding the condition of the heart muscle. And the remarkable thing about the method is that the diagnosis may be performed with the patient in a distant room or building, the necessary connection being established through a line of electric wiring.



Portion of an electrocardiogram and an enlarged section of the same showing the characteristic features of each cardiac cycle.



While the coarser features of the characteristic movement of the galvanometer string can be followed by eye for purposes of obtaining an exact record of all the finer features it is necessary to resort to photographic registration. The magnified image of the string is projected by means of a powerful electric light upon a slit in a dark box containing a moving photographic film. Ordinarily a film of half the length of an ordinary Kodak film is sufficient for one observation. Occasionally, however, much longer photographic films may be employed. A lever connected with a chronometer marking fifths or tenths of a second oscillates before one end of the slit so that a series of marks appears upon the film and clearly indicates the lapse of time corresponding to the several motions recorded upon the film. The record thus obtained is called "electrocardiogram."

Manner of attaching the electrodes to the patient.

View of the apparatus at the heart station.

Details of the heart station.

In the foreground are two arc lights. On the second table is placed the large galvanometer, for taking electrocardiograms, and the small galvanometer for registering heart sounds. On the wall is a telephone switchboard with connections to wards. On the third table is the multiple switchboard for making the various connections of the electrocardiograph.

One can, if desired, also record simultaneously on the same film a sphygmographic curve of the carotid pulse by placing before the slit a lever connected with a drum and receiver. But another expedient for this purpose is registration of the carotid pulse by means of a telephone and a second smaller galvanometer, the string of which is projected on the same slit. If desired, a third galvanometer may be used in connection with a microphone, and an electrophonographic record (or "cardiophonogram") of the heart sounds be made simultaneously with the electrocardiogram and carotid sphygmogram upon the film. This means that by the aid of the galvanometer and its auxiliaries the conditions of the heart and arteries can be investigated simultaneously in at least three different ways. (1) As regards the electrical changes in the heart muscle, (2) as regards the pressure changes in the carotid artery, and (3) as regards the sounds produced in the heart during activity or while it is at rest. Yet, as stated, the patient while the examination is being made, may be at a considerable distance from the heart station. Thus the electricity in the body of a patient in the hospital in Leyden, one and a half miles away, has revealed important facts regarding the condition of his heart to the physicians working in Einthoven's laboratory of physiology.

The apparatus in the heart station includes a whole series of different instruments, and is employed for the observation and recording of heart excitation and pulsation, heart sounds, pulse waves, blood-pressure etc., with a view of determining if the heart is healthy or diseased, and the station is remarkable for the delicacy and compactness of the apparatus which is accomplishing such results in the aid of medical science.

In operation the connection of the patient with the station is naturally of much importance, so that the current generated by the heart may be transmitted without loss if possible. The patient places left arm, left foot and right arm in three electrodes, which consist of zinc pans filled with normal salt solution of a strength of 8 grammes to the liter, or they may be made of German silver plates covered with felt and soaked in salt solution. From each of these, wires are conducted to three switches, by means of which any two of the electrodes can be connected to

DIAGNOSING HEART DESEASES BY ELECTRICITY

Abstracts from Current Periodicals

Phases of Science as Other Editors See Them

Maintaining the Stability of Aeroplanes by Means of Gyroscopes

THERE are serious objections to the employment of gyroscopes for maintaining the stability of aeroplanes in the manner in which they are employed on the mono railway and in some experiments with nautical vessels In order to utilize the peculiar property of the gyroscope on an aeroplane it must be used as Capt Lucas Girardville has used it to operate special stabilizing devices in the manner of an auxiliary motor The principle of this application and the experiments made by Capt Lucas Girardville are described in a recent issue of *La Nature*, from which the following account is condensed

If a gyroscope, with its axis of rotation initially in the line *OZ* (Fig 1), its pivot at the point *O*, and entirely free to oscillate in all directions about this point, is acted on by a force which tends to turn the axis of rotation toward *OY* the axis will resist the effort and will move toward *OX* oscillating slightly to each side of the plane *ZOX* This oscillation is called nutation The value of the nutation is inversely proportional to the rapidity of rotation and is therefore negligible for great angular velocities

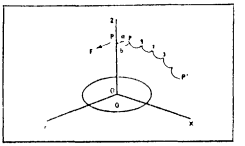

Fig. 1.—Principle of the gyroscope.

G gyroscope, OX, OY, OZ, axes of rectangular coordinates, PF, deviating force, Pp precession, ab, nutation

of the gyroscope The rotation of the gyroscope around *OZ* toward *OX* is performed at a nearly constant rate This movement, which is called precession is utilized for the operation of rudders by means of which the equilibrium of the aeroplane is maintained

The gyroscope is mounted in a carter which turns on two trunnions about an axis perpendicular to the axis of rotation The line of the trunnions is parallel to the direction in which stabilization is sought For example, if the line of the trunnions is parallel with the line of flight, any tendency of the aeroplane to pitch or tear will be counteracted by an elevating rudder operated by the reaction of the gyroscope The motion may be communicated to the rudder by a cord passing around a pulley attached to one of the trunnions (Fig 2)

The efficiency of this system has been shown by preliminary experiments in which the gyroscope and the rudder were mounted on an oscillating frame resembling the beam of a balance the carter turning on an axis parallel to that of the beam (Fig 3) The rudder was exposed to a uniform current of air produced by a blower and the apparatus was adjusted so that it remained in equilibrium In these conditions, if one end of the balance was depressed by the addition of a small weight or by touching it with the finger, the gyroscope, by means of a movement of precession about the axis of the carter acted upon the rudder in a manner so that the pressure of the current of air upon the rudder restored the equilibrium The apparatus was found to be so exceedingly sensitive that it was necessary to damp the oscillations by means of a plunger and a cylinder filled with water Experiments performed with aeroplane models showed that even with only 130 square feet of sustaining surface the reaction of the air upon the aeroplane made the hydraulic brake unnecessary, it was demonstrated that in free flight an aeroplane

would not oscillate appreciably under the action of the gyroscopic governor

The gyroscopic governors always operated in the proper direction with sufficient energy to restore the equilibrium whether the equilibrium was disturbed by changing the distribution of the load, or by employing irregular currents of air

Capt Lucas-Girardville is now engaged in constructing and adjusting, at the Military Aviation Park at Vincennes, an aeroplane equipped with gyroscopic stabilizers In this apparatus a large bearing surface of nearly 1,100 square feet has been combined with remarkable strength by means of a special construction The main frame is a vertical pyramid of bamboo, which forms the central support of a great circle made of steel tubes, attached to the frame by means of three systems of radiating steel wires (Fig 4) This apparatus, which closely resembles an immense bicycle wheel 23 feet in diameter, is very strong and rigid At two opposite points of the circumference are attached two projections which resemble the wings

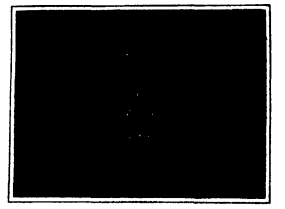

Fig. 4.—Circular frame of experimental aeroplane.

of an ordinary monoplane The large circle and the two wings, covered with canvas, constitute the upper plane of a biplane, of which the lower plane is formed of a much smaller rectangular surface, the width of which exceeds its length (Figs 5 and 6)

Two 70 horse-power Gnome motors of the new type are employed, placed in front of and behind the aeroplane in the line of motion These two motors, which are independent of each other, rotate in opposite directions in order to eliminate gyrostatic action in turning One motor drives a right-handed, the other a left-handed screw propeller. Hence the two motors, with their propellers, assist each other, and if one breaks down the other allows the fall of the machine to be retarded and made more gentle

The longitudinal stability of the apparatus is maintained by means of gyroscopes In the first experiments the gyroscopes were driven by the motor by means of flexible transmissions and friction rollers, but this arrangement has been replaced by an aerodynamic system, in which the energy consumed by the gyroscopes is furnished by a small auxiliary propeller exposed to the wind produced by the main propellers

The gyroscopes rotate at enormous speed, performing about 6,000 rotations per minute. As they are intended to assure longitudinal stability, they are so arranged that their movement of precession is performed about an axis parallel to the course of the aeroplane In these conditions, when the machine tends to pitch or rear, the axis of the gyroscope turns to right or left and operates a rudder which restores the equilibrium.

No attempt is made to supersede the human pilot in the control of the elevating rudders. The object is simply to correct temporary instability or a mistake made by the pilot.

By employing two gyroscopes both longitudinal and lateral stability can thus be assured to a certain extent. One gyroscope, with its axis of precession longitudinal, would control auxiliary elevating rudders, while the other, with its axis of precession horizontal and perpendicular to the line of flight, would move ailerons or warp the principal planes. In this application of the gyroscope to maintaining the stability of aeroplanes, it must be remembered that the gyroscope acts indirectly by operating moving parts, the effect of which can be increased, diminished, or annihilated at will by the pilot, by means of similar organs under his own control The gyroscopes do not exert any direct influence upon the aeroplane, because they are not rigidly attached to it

The problem, indeed, is very different from that of the mono railway, in which it is required merely to prevent the car from falling over sidewise, while the rail maintains longitudinal stability by presenting a line of support which prevents the vehicle from pitching or rearing A gyroscope, rigidly attached to the car, prevents the lateral overthrow of the vehicle by endeavoring to perform a movement of precession in a perpendicular direction, which is prevented by the presence of the rail In a freely flying aeroplane such an apparatus would cause the vehicle to capsize

Lupus and Its Treatment

AMONG the bacterial diseases of the skin, lupus is characterized by its extraordinary prevalence and the production of very deep lesions, which permanently disfigure so many faces In the scientific department of the Dresden International Hygiene Exposition the ravages of lupus are illustrated by a series of wax models which, according to *Hygieia*, show the social and economic importance of the diseases more convincingly than words could do According to the statistics of the German Health Bureau, 11,854 cases of lupus have been treated by German physicians since November, 1908 More than two-thirds of the patients were women

Lupus is treated in various ways Volkmann's method consists in scraping the affected parts with a sharp spoon, Thiersch employs excision and transplantation; while Hollaender recommends treatment with hot air and with Roentgen and radium rays The tuberculin treatment of Koch and Finsen's light cure are the most successful methods yet known. Finsen's celebrated institute was opened in Copenhagen in 1907 The great advantages of the Finsen method over others are that it is almost entirely painless and leaves no scars, except in places where the skin has already been destroyed. The apparatus employed by Finsen consists of a very powerful electric arc lamp of 30,000 to 40,000 candle-power, the rays of which are concentrated by quartz lenses The radiant heat is largely absorbed by a water cooling device As experiment has shown that the effective

ways are absorbed by the blood, and pressure is applied to keep blood from the surface. A hollow quartz lens, traversed by a continuous stream of cold water, is pressed firmly upon the diseased skin. The patient and the physician and attendants wear dark glasses to protect their eyes from the blinding light. Although the Finsen method is very successful, it suffers from the defect of requiring a long course of treatment which, in extensive development of the disease, may occupy many months, as only a fraction of a square inch can be treated each day.

A great advantage in this respect is possessed by Koch's tuberculin treatment, which rapidly dries up the pustules and checks the disease no matter how great its extent. The principle of the tuberculin treatment is the formation of protective bodies which kill the bacteria in the skin. The progress in the treatment of tuberculosis of the lungs has recently led to a new endeavor to combat lupus. Despite the progress that has been made, proper care for the unfortunate patients, whose disfigurement makes life a burden to them, demands the establishment of homes where they can find shelter and treatment. These homes could be partly supported by the work of the patients, according to their respective abilities.

The Great Waterfalls of the World in Their Relation to Industry and Conservation

THE waterfalls of the earth have become the subject of a conflict which is yearly increasing in violence. The lovers of nature wish to preserve the waterfalls in their original condition as far as possible for all time, while the engineers and industrial promoters seek to exploit them as sources of cheap power for electro-technical purposes. The accomplishment of this object on a large scale necessarily involves the total destruction or serious injury of the waterfalls, regarded as picturesque additions to the landscapes. It is only within recent years that waterfalls have been considered from the commercial point of view, but since it has been recognized that the energy of flowing water in very many cases furnishes a cheap and almost inexhaustible substitute for coal, which is yearly becoming more costly and more largely consumed, the great waterfalls which, as impediments to internal navigation, have hitherto been worse than worthless from the viewpoint of social economy, have suddenly become objects of very great value. The falling water drives the turbines of electrical power stations, producing electric light and power which, in many cases, is transmitted over hundreds and even thousands of miles. The war over the waterfalls which is now being waged by the friends of nature and the promoters of industry is likely soon to increase greatly in bitterness, for many celebrated falls have already been destroyed, or have at least suffered serious æsthetic injury, from the establishment of power stations. The famous Falls of the Rhine, at Schaffhausen, are at present the subject of heated controversy. Several power stations already stand on their banks and sap their life blood. The Swiss government, however, takes care to preserve a sufficiently large volume of water to maintain the character of the falls as a notable spectacle and an attraction for tourists. A still more bitter strife has been engendered in America by the question of the preservation or destruction of the Falls of Niagara. These famous falls have already narrowly escaped entire absorption in the pipes of power stations and very energetic action on the part of lawmakers, both in the United States and in Canada, has been required to keep intact from industrial invasion and preserve, in its original beauty, at least a remnant of this great wonder of the world.

Another North American waterfall which, as the highest fall in the whole world, especially deserves preservation as a natural monument, is apparently assured against destruction for all time. This is the Yosemite Fall in California, which makes a descent of 2,600 feet in three successive stages. As the whole Yosemite Valley, which was not discovered until 1851, was made a national park in 1864, the Falls of the Yosemite are under governmental protection and their pristine beauty can never be marred by the establishment of any power station.

There is a popular but erroneous impression, says Dr. Richard Herring in an article which is here reproduced from *Ueber Land und Meer*, that the Falls of Niagara are the greatest in the world, and even those more enlightened persons who know that the Victoria Falls of the Zambesi River in Africa are twice as broad and more than twice as high as those of Niagara, almost invariably assign to Niagara the second rank among the great waterfalls of the earth. Even this is an error, for South America possesses a waterfall which exceeds Niagara both in width and in height, and is actually the second largest waterfall in the world. This little known waterfall is that of the Iguassu River, a tributary of the Parana, and like Niagara it is situated at the boundary of two States, each of which owns half of it. The total water power of the Iguassu Fall, which is 213 feet high and nearly two miles wide, is estimated as about fourteen million horse-power. This is approximately equal to the aggregate water power of all Scandinavia, which is so rich in waterfalls, or about ten times the total water power of Germany. The temptation to exploit this great, inexhaustible, never-freezing stream as a source of power for industrial purposes may easily be imagined. At present such exploitation is quite impossible, as the Iguassu Fall is too far from the beaten tracks of commerce to make it profitable to establish any electrical power station, but it will probably not be long before these falls will be threatened with the fate of Niagara. This undesirable possibility has been foreseen by the interested States, Brazil and Argentina, which have already begun negotiations designed to protect the falls.

The largest of the earth's waterfalls, the Victoria Falls of the Zambesi River, in Rhodesia, which are 386 feet high and more than a mile wide, and which were discovered by Livingstone in 1855, have also become the subject of a compromise between the conflicting demands of the lovers of nature and the promoters of industry. The water power of these falls is estimated to be fully thirty-five million horse-power, two and one-half times that of the Iguassu, and five times that of Niagara. By way of comparison, it should be noted that the aggregate water power of the whole of Europe cannot greatly exceed thirty-five million horse-power. It is certainly possible to derive a few million horse-power from this great fall without appreciably detracting from its majestic beauty. The demands which are made at present are still more modest. The Victoria Falls Power Company ask for only 150,000 horse-power, less than 1/200 part of the whole, and the plans for the future development of the station involve no danger of the annihilation of the falls. The British government and the colonists know very well that the Victoria Falls, which since 1905 have been easily reached by the Cape-to-Cairo Railway, which crosses the Zambesi immediately in front of the principal fall, will certainly bring as much money into the country by attracting tourists as by producing electrical power.

There is no other waterfall in the world which is at all comparable in greatness with the Zambesi, Iguassu, or the Niagara. Asia, notwithstanding its colossal mountain ranges, is comparatively poor in large waterfalls which are found most abundantly in Africa and North America. The largest African streams, especially, are interrupted by many falls of considerable height. The Congo has several high falls which, owing to the great volume of the river (about sixteen times that of the Nile), may be counted among the most important sources of water power on earth. The Stanley Falls, in the middle reach of the river, consist of seven successive falls, of a total height of 164 feet and a width of nearly 4,000 feet, and offer an exceedingly rich source of power which probably will soon be exploited. Still more important is the total water power which the Congo develops in the non-navigable section extending from its mouth to Stanley Pool. Here the river, confined in a channel only a few hundred yards wide, and with a depth of water of nearly 300 feet flows with a velocity of 48 feet per second so that at every point of the stream 25,000 to 30,000 cubic meters, or about a million cubic feet, of water are hurled along with irresistible force, while thirty-two rapids and waterfalls lower the level of the stream by 829 feet in a stretch of 170 miles.

The lower Nile in Egypt possesses a series of rapids, the celebrated Cataracts of the Nile, but no waterfall in the strict sense of the word. True water falls occur on the upper Nile, the most beautiful of them at the point where the stream issues from Lake Victoria Nyanza. This Ripon fall is only a few yards in height, but the volume of water is so great that it presents a magnificent spectacle.

Comparatively few persons know which is the highest waterfall in Europe. The most voluminous of European waterfalls, strictly so called, are the Rhine Falls at Schaffhausen, but the highest are the Rjukan Falls of the Maan-Elf River, in the Norwegian province of Telemarken. The principal fall is 800 feet high and the total height of the two chief falls with the intervening rapids amounts to 1,837 feet, while the average flow of water is 50 cubic meters, or 1,760 cubic feet, per second. The largest water power station yet projected is here being developed by the Badische Anilin und Sodafabrik, in conjunction with other firms, for the fixation of atmospheric nitrogen. The Rjukan Falls, with their total energy of 250,000 horse-power, are already things of the past, for they have been irrevocably perverted to industrial uses. A similar fate threatens other small Norwegian falls, but Norway is so rich in waterfalls that it can well spare a few. In Sweden, likewise, the Falls of Trollhatta, the most celebrated of all Scandinavian waterfalls, have been almost entirely annihilated as objects of natural beauty. Nearly all of their water is now employed for the production of electricity. The government itself has recently established here a power station with a capacity of 40,000 horse-power. This, now the largest water power station in Europe, will soon be surpassed, however, by the station at Rjukan in Norway and by a still larger station in the north of Sweden, which will serve for the operation of the Lofoden Railway.

The Porjus Fall, at which this last-mentioned station will be placed, is only one fall, or rather rapid of a long series formed by the Lule Elf, near its source in the lake region of Lapland.

The largest and most beautiful of these falls is the celebrated Harsprang which forms the subject of many legends. The Porjus power station is expected to reach completion in 1914 and to develop soon afterward about 80,000 horse-power, yet the wild beauty of the Porjus Fall will be little affected as it is estimated that its total water power in summer after its sources of supply have been regulated, will be about 300,000 horse-power. In the Porjus Rapid the river descends 164 feet in about 2 miles. The Harsprang is also half waterfall and half rapid and accomplishes a descent of 244 feet in 1¼ miles. The Harsprang would therefore yield more power than the Porjus, but it is to remain untouched for the present, and it is to be hoped that it will be forever preserved as a natural monument. Sweden, with its great wealth in water power, can well afford such a luxury. Even little Finland is endeavoring to preserve natural beauty and has decided to keep her greatest waterfall in its original condition as a natural monument, and to allow no large power station to be erected on its banks. This fall is the celebrated Imatra Fall of the Wuoven River. The total descent is only 66 feet in two miles, but the volume is very great and the depth considerable while the width of the stream contracts from 570 to 150 feet in the course of the falls.

Some Engineering and Economic Results of the Commercial Motor Vehicle.

THE *Engineering News* recently expressed the opinion that "The commercial motor vehicle must be able to show an all-around saving in the cost of doing a given task before it can expect to find favor as compared with the horse-drawn vehicle."

Further, it states, the motor-vehicle must make a very substantial saving over the simple, cheap horse drawn vehicle in order to win success. Any motor-vehicle equipment is going to require a large investment compared with horses and wagons and the purchaser must be shown a good profit on this investment after the items of depreciation and repairs are provided for.

"The average merchant, or manufacturer or contractor is not going to make a large investment in motor trucks or motor delivery wagons unless these vehicles can earn a good deal more than six per cent net on their first cost. Most concerns are borrowing money at that rate to use in their business."

At the present time however experience accumulated from many sources appears to show that there are commercial motor vehicles now on the market which can, under favorable circumstances show a large saving over the cost of working with horse drawn vehicles.

The great advantage of the motor vehicle is that it can run at higher speed and carry heavier loads than any vehicle drawn by horses. Every engineer who has made an analytical study of the cost of wagon traffic knows that one of the largest items in the ton mile cost of freight haulage over common roads is the wages of the driver. It is an interesting fact that the lowest ton-mile costs for haulage by wagon over common roads in the United States are not made over the improved roads of the East. They are made in remote districts of the West, still beyond the reach of railways, where goods have to be hauled long distances over the crudest sort of highways and where the volume of traffic is such that teams of eight or a dozen or more mules are used to a load and one driver manages a load of several tons.

"It will be apparent from this that one of the most hopeful fields for the use of motor trucks is in any industry where the volume of traffic permits heavy loading and long hauls. The motor vehicle will make a better economic showing in heavy trucking, for example, than in light delivery wagon service. In the latter service again, the advantage will be much greater if run on a suburban and country route, where distances are long and stops are few, than on a city route, where a small area is covered."

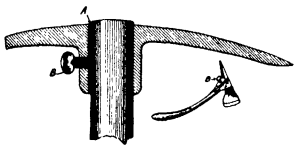
HANDY MAN'S WORKSHOP

[The Editor of Handy Man's Workshop will be glad to receive any suggestions for this department and will pay for them, promptly, if available.]

A Simple Turnbuckle

By William Grotzinger.

A SIMPLE turnbuckle which I devised and used on my monoplane glider can be easily made as follows. Take the spokes and nuts out of an old bicycle



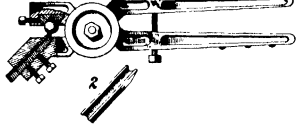
Turnbuckle made of a bicycle spoke.

wheel. Twist the wire at the unthreaded end, so as to form a loop to receive one end of the bracing wires. For the other end, cut a strip from a piece of sheet iron, 3 inches long and ⅝ inch wide, punch a hole in the center to receive the threaded end of the wire. Punch a small hole at each end of the strip to receive the other end of the bracing wires. Now bend the strip as shown in the illustration, and put the nut in place. You will then have a small, neat, strong turnbuckle, which can be used for many purposes.

Adz-tightener

By W. A. Lane

AT its best, an adz is a rather dangerous tool to use, and to have it work loose is nearly certain to end in disaster. A tightener as shown here is not expensive, can be put on any adz, and will last as long as the adz itself. On the upper edge of the head drill a hole and tap for a ⅜-inch set-screw as



Adz-tightener.

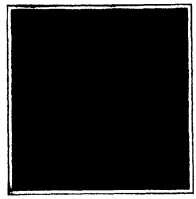
shown in the drawing. Have the square head on the set-screw flattened like a thumb screw, so that you can tighten or loosen it with the claws of your hammer. Next, make a thin strip of iron the width and length of the upper side of the eye. The set-screw bears on this iron strip and makes the pressure on the handle even.

Turning Ball Joints to Gage

By C. G.

IN Handy Man's Workshop of April 1st, there was a description of a method of machining ball and socket joints. The writer is of the opinion that the tools used in the method described would be apt to

Device for turning balls to gage.



become dull in a comparatively short time, and then could not be sharpened without altering the gage. A friend of the writer recently designed the device shown in the accompanying sketch, which overcomes the difficulty. The cutting tool used is shown in perspective in Fig. 2. It will be observed that it consists of a bar with a channel in the upper surface which is of such shape that when the bar is cut off at an angle of 45 degrees, a cutting edge will be formed that will be a true semicircle. The tool is used in a device somewhat similar to a pair of pliers, as indicated in Fig. 1. In one of the jaws of the pliers is a bearing block with a pyramidal socket to receive the ball, while the cutting tool is mounted at an angle of 45 degrees in the other jaws of the pliers, with its cutting edge centrally disposed under the bearing block. With the shank of the ball end secured in the chuck of a lathe, the pliers are placed over the ball in the position indicated, and then the handles are pressed together until stopped by an adjusting screw, the tool in the meantime cutting the ball to standard gage. When the tool wears down, as will be the case after a few balls have been turned, it may readily be sharpened, provided the same angle is always preserved at the cutting edge.

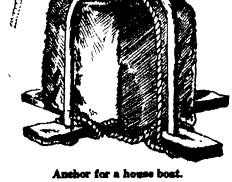
An Improvised Bobbin Winder

By Henry H. Riggs

HAVING wasted much time winding small bobbins by hand for lack of a lathe, the last time I had to wind one it occurred to me to make use of a common drill brace, which proved so satisfactory as a bobbin winder that I pass the idea on to other amateur electricians whose outfit is limited as mine is.

The method is shown in the photograph. A drill shank or any bit of heavy wire will answer as a spindle to mount the spool on. If it does not fit the hole in the spool, wrap it with paper till it does, snugly.

Improvised bobbin winder.



If a vise is not available, the brace can be clamped to the edge of the bench with a screw or two while the winding is being done.

A large spool of heavy wire can better be wound with a common carpenter's auger brace. The spindle on which the spool is slipped should be longer than the spool. The end is then supported by inserting it in a hole bored in the edge of the bench, while the butt end of the brace is supported in its traditional place in the "pit of the stomach." This leaves both hands free for winding.

Home-made Anchors

By Albert F. Bishop

HERE are two ideas that may be useful to the handy man who owns a boat, but doesn't own a suitable anchor. One of the illustrations shows an anchor of the conventional form, but made of wood and stone. A piece of wood with a natural bend is used for the fluke piece. The ends must be pointed and two holes must be bored through it, about 4½ inches apart, to receive two sticks of very hard wood. Each stick should have a knob on one end to keep it from drawing through the fluke piece. A stone should be placed between the sticks which may be sprung so as to em-

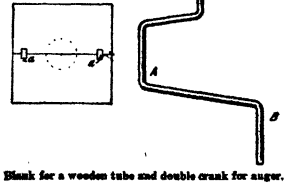
Anchor for a house boat.

brace the stone tightly. The sticks should then be well seized close to the stone and also at the upper ends. Anchor ropes are usually fastened to the fluke piece and thence pass up to the ring or loop, being seized there with a small cord. When pulling up the anchor this cord will break if the anchor is caught in the rocks. The rope will then capsize the anchor and probably release it. The writer saw this anchor on the bank of a river and thought it a very clever idea. The holding qualities looked very good.

The other anchor illustrated here is adapted particularly for houseboats. A cross of wood is made and holes are bored near the ends. A square weight is laid on the cross, and bows of hard wood are inserted in the holes and are drawn down tightly on the stone. The ends of the bows are well secured by means of hard-wood wedges. The rope is fastened to the cross

Wood and stone anchor for small craft.

and seized with a cord to the junction of the bows. This anchor was used by the captain of a small craft. He felt very secure when anchored with this home-made device.



Making a Wooden Tube

By W. D. Graves

IN the days when iron pipe was more expensive than it now is, and wood cheaper, it was a common practice to bore logs lengthwise and to use them for carrying water underground, often for long distances. It was an easy matter to bore accurately in the center of logs because, in the kind of wood chosen for the purpose, a small open or pithy "heart" extended through it. This was very small, usually but little larger than a pin, but it was sufficient; for the worm of a bit found it to be "the line of least resistance" and would follow it. While this sort of wooden pipe is rarely to be desired, nowadays, it is sometimes desirable to have a wooden tube and to know how to make it. By making it in two parts one may arrange to guide the bit in much the same manner as did the old time aqueduct makers, and even more accurately.

These parts should be gotten out as shown in end view in the drawing, the two inserted tongues, *a*, *a*, serving to hold them relatively in place and to make the joint tight. Along what is intended for the center of the hole a deep gage mark is made, and, with a corner chisel or other tool, a small triangular section is removed for the whole length so that when the two parts are clamped together a small square hole will extend through where the center of the final hole is to be. The size this "pilot" hole should be depends upon the size of the bit or auger to be used. For a large auger it will not need to be more than an eighth of an inch square, and for a small bit the gage mark alone will often be found sufficient. It must be large enough so that the point of the worm will enter it, but small enough so that the bit will be firmly guided and drawn forward.

When boring the parts must be very firmly held together and the bit must be drawn out as often as the pod fills with shavings. For the latter reason it is advantageous to have a bit with as long a pod as

Blank for a wooden tube and double crank for auger.

is available. The shank of the bit is best lengthened by welding a steel rod to it. For turning it a common brace may be used; but if much work of this sort is to be done, it will be found to be accelerated by having the end of the rod bent into a double crank, like that commonly used on "ship augers," as illustrated. This is operated by taking hold at *A* and *B* with each hand. It requires a little practice to enable one to turn the cranks thus without making the bit wabble considerably; but as soon as one gets the knack he can do the work much faster than with a brace, and much more easily.

The Inventor's Department

Simple Patent Law; Patent Office News; Inventions New and Interesting

The Use of the Electro-magnetic Separator in City Refuse Disposal

THE magnetic separator is now largely used in various fields of industry, and is found to be of much efficiency in saving time and labor. It is employed to separate magnetic from non-magnetic material in a mixture of the two.

It is of value in handling coal, rock, and ore when it is essential that no large pieces of steel or iron should enter the crusher. It is also made use of for removing iron shot from molding sand, for separating brass chips from machine shop turnings, and for separating magnetic ores. This form of separator is also particularly useful in taking out the bits of iron or steel found in all sorts of junk, such as leather goods, rubber and rags, which must be removed before the material is worked over into new products, since if allowed to remain they would deleteriously affect the material or be a source of injury to the machinery.

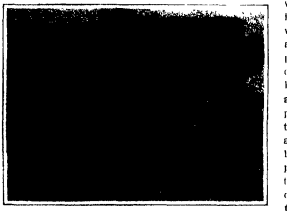
Still another application is the use of the separator in grain elevators, cereal plants and flour mills. Before its installation much damage was caused to mill stones and other apparatus by the fragments of wire found in the grain as a result of the use of modern binders and reapers.

There are various more or less elaborate forms of separators, the simplest being the separator roller. The roller shown in the accompanying illustration consists of alternate coils and steel disks concentric with the shaft. The coils are wound on steel spools doweled to the disks, and the disks are in their turn keyed to the shaft.

Each coil is inclosed and protected by a cylindrical brass coil shield having a tight fit on each of the two adjacent poles. Current for the coils is obtained through carbon brushes held by self-adjusting holders on a pair of slip rings, at one end of the shaft.

These rollers are regularly built 12 inches in diameter, in lengths from 16 to 36 inches, and are driven by an electric motor mounted on the base of the machine. They have a current consumption of 325 to 750 watts, and capacities of 1,340 to 3,000 cubic feet per hour. They are designed to operate on any direct current voltage up to 250. They are usually installed as a part of a conveyer belt system.

The material falls from a hopper upon an endless moving belt below, and is carried along till it reaches the magnetized roller. The non-magnetic material being unattracted, is thrown off by centrifugal force to a bin or upon another conveyer belt, while the magnetic material attracted by the roller is held until it passes beyond the magnetic zone of the same on the under side, where it drops into another receptacle below.



A novel and interesting application of this device is its use in garbage reduction plants. All city refuse contains a very considerable percentage of iron, chiefly in the form of metal cans, etc. It is very desirable to have this eliminated both because of its own value and to rid the other material of it.

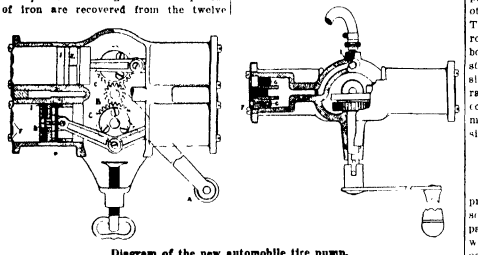
The Borough of Richmond of the city of New York has recently installed a magnetic separator roller for this purpose, which has been running successfully for several weeks. It is believed to be the only one in the United States used for such a purpose, though several are in use in Great Britain. Mr. J. T. Featherstone, the superintendent of the Street Cleaning Department in Richmond Borough, gives some interesting data concerning the practical working of the separator.

The dimensions of the separator are 24 inches by 12, all the rollers being 12 inches in diameter. The cost of operation is very low, since one horse-power or less is sufficient to operate it, while the cost of the roller itself is not much over one hundred dollars.

About thirty tons of raw material daily are used. This is run through a furnace which melts it down into about twelve tons of clinkers, destroying at the same time the animal and vegetable matter. This, of course, is one of the main objects in city waste disposal, for sanitary reasons.

The clinker is then run through a crusher, and the resulting product passes onto a belt which carries it over the roller. On an average about 600 pounds of iron are recovered from the twelve tons of crushed clinker. The non-magnetic residue is used in the manufacture of concrete to take the place of broken stone and sand, and the process is especially valuable because the iron if allowed to remain would spoil the appearance of the concrete by a peculiar stain. It is probable that this process will be followed in other communities, when its simplicity and efficiency become known.

A new automobile tire pump.



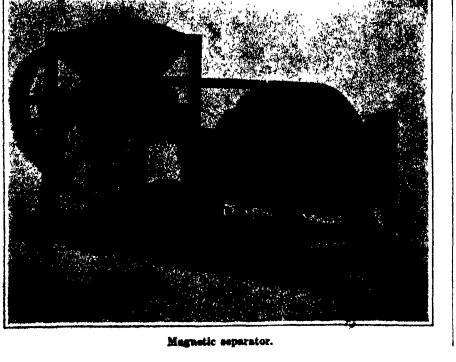


Diagram of the new automobile tire pump.

Magnetic separator.

A New Automobile Tire Pump

OUR illustration shows a new form of portable four-cylinder hand pump especially adapted for inflating automobile or motor-cycle tires. The aim which the inventor had in view in designing this pump was to provide a portable apparatus which could be readily attached to a suitable support such as the step of an automobile. The pump is furthermore so constructed as to combine great strength with simplicity of structure, so that it can be manufactured at a low cost, and is efficient and reliable in operation. The air passages are so formed as to avoid joints, which would be apt to become loose and to leak. With these objects in view the frame has been made in one single casting, consisting of a vertically disposed wall and cylinders integral therewith on opposite sides of the wall, the cylinders being disposed in axial alignment. Pistons reciprocate in these cylinders, being actuated by a handle *A* which is journaled centrally with respect to the cylinders in the central vertical plate. Suitable valves *D* admit air to the cylinders for compression and permit the escape of the air when properly compressed.

The passages for conveying the compressed air from the cylinders to the point of consumption are formed directly in the casting constituting the frame of the pump. Valves *G* are arranged in these passages for the purpose of preventing the return of the compressed air to the cylinders, and these valves as well as the intake valves *D* are so constructed that the use of ample lubricating oil in the cylinders will not result in the incomplete closure of the valves. The air inlet valves *D* are mounted upon each of the pistons and are automatically opened by suction by a friction operated piston ring *E*, during the return stroke of the piston. All four cylinders are arranged in opposite pairs with separate head plates. A powerful screw clamp is formed integral with the cylinder casting by which means the pump is readily attached to the running board. The pistons are operated by means of pinions *C C*, which have twice the number of teeth as the intermediate pinion *B* so that the clamp motion is geared down to the ratio of two to one.

Each of the driving gear wheels is screwed to a crank shaft and from the crank pins, connecting rods secured to pistons on opposite cylinders. The two crank pins are arranged at right angles to each other, so that when one pair of pistons is at the end of the stroke the other pair is approximately at mid stroke. The gears are cut gears. The connecting rods are made of manganese bronze. The bore of the cylinders is 1¾ inches and the stroke 2 inches, equivalent to an 8 inch single stroke, and as the pump is so arranged that the compression strokes come at equal intervals, the pump is remarkably easy to operate, especially since the crank handle is quite long.

Notes for Inventors

The Money in Little Things.—The profits resulting from patents of limited scope frequently come to the notice of patent attorneys in active practice. The writer recalls an instance in which the patentee of a harvester knife grinder submitted the patent for an opinion as to its scope. When told that the patent was limited very closely to the structure it presented and that almost a "Chinese copy" would have to be made to infringe it he said "That may be so, but I have made seven thousand dollars out of that patent in the last three months in the territory west of the Mississippi." Possibly his wits had been sharpened by the grinding operation, for we recall an itinerant scissors grinder of the Irish persuasion who opened the office door one day and called out "Has yez anything to sharpen up to day?" to which one of the office force replied "No! unless you can sharpen up our wits," and the answer came quickly back, "I have no stones small enough for that."

The One Millionth Patent.—Patent number one million will issue shortly, probably about the middle of August. The first patent of the present series was issued July 28th 1836 to John Ruggles (antedated July 13th, 1836) of Thomaston, Me., for a locomotive engine. One hundred and nine of the patents of the present issue were issued prior to January 1st, 1837, but these one hundred and nine patents were not regularly numbered on the patents themselves although the original drawings and the specification in the Patent Office are regularly numbered. On January 1st, 1837, however, the patents began to be regularly numbered with patent one hundred and ten issued on that day, and the numbering has con-

tinued until the present time. It will thus require only a little over seventy-five years to complete the issue of one million patents. Prior to July 28th, 1836, 9,957 patents had been granted. These patents have never been officially numbered but were numbered in their order by Examiner-in-Chief Skinner when he was in charge of the classification division of the Patent Office. It has been suggested that some ceremony be attached to the delivery of the one millionth patent but nothing definite along this line has as yet been decided.

A Woman's Patent.—Patent No 1,148,053 should be of interest to women because it is for a combined bread toaster and warming oven for use on gas stoves. Apart from any particular interest in the invention itself, the patent is notable because it was issued to a woman inventor, Minnie Agnes Phelps of Chicago, prosecuted by a woman attorney of Chicago and witnessed by two women.

Storing Patent Assignments.—The necessity of fireproof storage facilities for the assignment records of the United States Patent Office was called to attention in our issue of May 27th. The Fire Marshal P. W. Nicholson, of the District of Columbia has just submitted to the District Commissioners an extended report on the hazardous conditions existing practically throughout the Patent Office building. As to the general conditions in the Patent Office the Fire Marshal has this to say:

The worst conditions are on the third floor (9th Street wing). The entire floor and court do not taken up with combustible matter, wood shelving filled with official documents. The corridor is used by the public in the examination of records and the position of the official forces is obstructed by desks and tables.

There are two hallways extending from the floor to the ceiling filled with wood shelving in which are stored official documents with small niches hardly wide enough for one person to pass. The conditions are much congested. In the event of a fire the fire department would be much hampered by the obstructions from the corridors besides encountering a regular wall of fire. The stairways are hidden from view by the wood shelving and are not properly located. There are two who gates in this corridor, separating two different bureaus that are kept locked at night. This should not be allowed.

Concerning the storage of gasoline in a manner prohibited by the District regulations, the report says:

There is a small room in the basement 7th Street wing which is used for the storage of oils. I found in this room two cans each holding containing kerosene and one contain ing gasoline. The manner in which gasoline is stored should be abolished at once, as it is very dangerous. It is also liable to occur at any time, and if some person, not knowing the volatile conditions should strike a match a fire and probably an explosion would be the result. The regulations prohibit the storage of gasoline in this manner.

New Westinghouse Brakes.—A brake mechanism has been patented which has two winding drums. One of the drums takes up the slack in the chain and applies the brake shoes to the wheels, while the other drum applies the brake shoes to the wheels with the maximum braking power. Means are provided which are operated at a predetermined degree of braking pressure to cut the first drum out of action. The patent, No. 994,286, was issued to the Westinghouse Air Brake Company as assignor of Richard C. Swartzwelder of Edgewood, Pa. In a patent No. 994,220 Walter V. Turner of Edgewood, Pa. assignor to the Westinghouse Air Brake Company provides an air brake in which a number of brake valves act in connection with a single equalizing discharge valve device for the train pipe which is adapted to be operated by either brake valve, the brake va ves having ports and connections so they can control the pressure in the equalizing chamber.

Caffeinless Coffee.—Three reissues, Nos. 13,261, 13,262 and 13,263 have been granted of original patent No. 897,846, for the preparation or treatment of coffee in which the unbroken green coffee beans originally containing caffein, but freed therefrom, have their remaining natural constituents substantially unimpaired. In removing the caffein, the green coffee beans are treated with dry steam to loosen the molecular structure, then treated with gaseous chemicals to liberate the caffein from its salts, after which the caffein is extracted by a volatile solvent and the beans are subjected to currents of dry steam at different pressures.

The Cuspidors in the Patent Office.—Those who have visited the Patent Office will remember the large cuspidors that adorn the halls at intervals. It is told of a prominent Philadelphia lawyer of the old time that on one occasion he was sitting on the steps of the Patent Office nursing a lame foot. A Washington attorney asked what was the matter. He replied that he had been in and had a very unsatisfactory interview with a Patent Office examiner and it had been his habit when discussing patent matters before Congressional committees, if the results were unsatisfactory, to kick the rubber cuspidors then in use of the U. S. Capitol along the halls. On leaving the examiner's room after the unsatisfactory interview, he pursued the same tactics, thinking that the cuspidors in the Patent Office halls were also rubber, but he said with an exclamation "I found them to be cast iron and almost broke my foot."

The Need of an Easily Set Rat Trap.—Wasn't it Jay Gould who laid the foundation of a great fortune by the sale of rat traps? If so, and you have ever tried to set one of these five or ten cent affairs they sell in the department stores, you may well wonder why some one does not follow his example with a mouse trap that can be set without losing all one's religion.

Ross Turner as a Patent Office Draftsman.—A celebrity who was at one time an *attache* of the Patent Office is Mr. Ross Turner, the prominent water color artist. Prior to his European studies, Mr. Turner was a draftsman in the draftsmen's division. This, of course was many years ago but Mr. Turner is well remembered by some of the older officials.

Legal Notes

Color and Trade-marks.—In *ex parte* Austin, Nichols & Co., the Commissioner of Patents has held, affirming the decision of the trade-mark examiner, that where the applicant states that the color of the trade-mark is not claimed, the special lining of the drawing to indicate color should be omitted. Also that coffee and cocoa are goods of the same descriptive properties.

An Unfair Competition Decision.—The Supreme Court of the United States by Mr. Justice Holmes has delivered an opinion in the unfair competition case of Jacobs vs. Beecham, affirming the decision below and holding that the burden rests upon the defendant when sued for an unfair use of the plaintiff's name to justify his use of the name, also that the use of the name of a manufacturer of pills under a secret formula upon pills made by a competitor is not saved from being unfair because the name of the manufacturer is accompanied by a statement that the competitor makes the pills, even if it be conceded that he is using the others formula. The decision also refers to the use of the word "patent" as applied to proprietary medicines and holds that the use of the word "patent" to indicate a medicine made by a secret formula when the medicine is in fact not patented is not such a fraud as defeats the right of the manufacturer to relief in equity against unfair competition. In the decision it is said "The use of the word 'patent' to indicate medicines made by secret formulas is wide spread and well known. It is mentioned in the dictionaries and it occurs in the plaintiff's circulars."

RECENTLY PATENTED INVENTIONS.

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

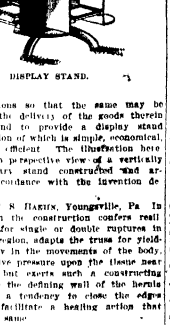
Pertaining to Apparel.

HAT.—D. STARR, New York, N. Y. This invention relates to hats, and it has for its object the provision of one having a separate crown member, which may be readily mounted on a brim member, so that hats of many different styles may be quickly provided by the selection of the desired crown member, to be used with the brim member which has been previously selected.

Electrical Devices.

SIGNALING DEVICE FOR TELEPHONE SYSTEMS.—A. J. DE STROP, Kirkhan, Alaska. The main object here is to provide a signaling system in which the signals may be sent to a considerable distance, as far as the line is likely to be used for talking purposes. A further object is to provide a system with simple apparatus, including a relay for producing audible signals.

Of Interest to Farmers.



SAFETY CHECK FOR CUTTER BARS OF MOWING MACHINES.—N. ROGERS, Wolfboro, N. H. The object of this inventor is to provide novel means for automatically and instantly stopping the action of the cutter bar while the mowing machine is being moved, at the time the driver vacates the seat, on the machine when said vacation is effected purposely or accidentally.

Of General Interest.

MARKING STAKE.—M. F. ROGERS, Cement, Wash. The intention of this invention is to provide a stake having a weight near its pointed end for steadying the stake, and so arranged that it cannot slip on the stake, even should it become loosened. A further object is to provide an improved holding means for the stake when not in use, with which the stakes may be easily connected and disconnected.

PACKER FOR WELLS.—A. C. GRAHAM, Oil fields, Cal. One object here is to provide a packer which may be inserted within the casing directly in position and which is left in place in the casing after the insertion of the cementing material. The cementing material will firmly lock the packer in place, and the lowering device may be disconnected from the packer without disarranging it in its position at the end of the casing.

DISPLAY STAND.—WALTER GILBERT, St. Louis, Mo. Among the principal objects which the present invention has in view are: To provide a revolving stand arranged and constructed to facilitate the handling and display of merchandise packed in cartons, to provide a simple and efficient means for delivering the cartons so that the same may be handled for the delivery of the goods therein contained, and to provide a display stand the construction of which is simple, economical, durable, and efficient. The illustration here with, shows a perspective view of a vertically disposed rotary stand constructed and arranged in accordance with the invention described.

DISPLAY STAND.

TRUSS.—P. S. HARDIN, Youngsville, Pa. In this invention the construction confers resilient support for single or double ruptures in the inguinal region, adapts the truss for yielding conformity in the movements of the body, avoids excessive pressure upon the tissue near the rupture, but exerts such a constructive pressure upon the defining wall of the hernia as will have a tendency to close the edges thereof and facilitate a healing action that will cure the same.

LOADING WIRE FOR TRAVELER DISPENSERS.—J. S. DRAKE, Lancaster, S. C. The object here is to provide means for supplying travelers to the dispensing device, by means

LEGAL NOTICES

PATENTS

INVENTORS are invited to communicate with Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D. C., in regard to securing valid patent protection for their inventions. Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured.

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our Hand-Book on Patents will be sent free on request.

Ours is the Oldest agency for securing patents; it was established over sixty-five years ago.

MUNN & CO., 361 Broadway, New York
Branch Office, 625 F St., Washington, D. C.

PATENTS SECURED OR FEE RETURNED
Free report as to Patentability! Illustrated Guide Book, and What To Invent, with List of Inventions Wanted and Prizes offered for inventions sent free. VICTOR J. EVANS & CO., Washington, D.C.

Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than ten lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

FOR SALE.

FOR SALE.—Complete set Patent Office Reports for the year 1836 to 1871 inclusive, bound volumes of Official Gazette from 1872 to 1900 inclusive, unbound volumes 1901 to date. All in good condition. Address P. O. Box B, Mamaroneck, N. Y.

HELP WANTED.

WANTED—GENERAL SUPERINTENDENT to take charge of a sheet metal stove shop employing 1000 men. Must be thoroughly familiar with sheet metal work, factory management and equipment. He must be strictly sober, efficient, constructive ability and be able to furnish first class references as to character, experience and ability. Only those who can fully qualify need apply. Address Supt. Box 773 New York, N. Y.

SUPERINTENDENT. Metal Department of a large manufacturing concern. Must be thoroughly understands the sealing and finishing of articles from sheet metals. No one who is not thoroughly experienced need apply. Permanent position to right party. Address Metal Expert, Box 773, N. Y.

PATENTS FOR SALE

FOR SALE.—Outright, U. S. patent 949,230, combination of series padlock and locking device for any article sold. Simple, attractive, durable. Small capital required. Unquestionable sale. John Junkunc, P. O. box 583, Pocatello, Ida.

FOR SALE.—I have invented a lead rule for cattle. Patent No. 1,184,. I desire to sell this patent for full particulars about this invention and other information, address, F. P. Williams, Jr., Bend, Oregon.

FOR SALE.—Patent No. 991,30. This is a joint fastener "Invisible" for window, screen, storm doors, etc. No nails or screws used. D. A. Wright, 316 4th St., San Antonio, Texas.

THE PATENTEE of No. 987,78, a metal device for holding paper targets, especially useful for indoor practice rifles, wishes to have same manufactured, or will sell patent or invest it in a factory. C. F. Worrell, Zanesville, Ohio.

WANTED.

LOCAL REPRESENTATIVE WANTED. Splendid income assured right man to act as our representative also learn how our business is conducted. Small amount experience unnecessary. All we require is honesty, ability, ambition and willingness to learn a lucrative business. No soliciting or traveling. This is an exceptional opportunity for a man in his locality to get into a big paying business without capital and become independent for life. Write at once. Universal Company, Address, E. R. Marden, Pres. The National Co-Operative Real Estate Company, L. 336, Marden Building, Washington, D. C.

MISCELLANEOUS.

FREE—"INVESTING FOR PROFIT" Magazine. Send me your name and will mail you this magazine absolutely free. Before you invest a dollar anywhere—get this magazine. It is worth $10 a copy to any man who intends to sell this month. Tells you how $1,000 can grow to $27,000—how to judge different classes of investments. Tells the Real Earning Power of your money. This magazine six months free if you write at once. H. L. Barber Publisher, 478, 30 W. Jackson Blvd., Chicago.

CIVIL SERVICE EXAMINATIONS open the way to good Government positions. I can coach you by mail at small cost. Full particulars free. Am a American citizen of eighteen or over. Write to-day for Booklet 8 G. M. Hopkins, Washington D. C.

FOOLISH! FOOLISH! is the man who neglects his Health to promote his business. $2 to $5 per day made. Gold Seal Secret. Special postal for descriptive circular. E. M. Davis Co., Desk 8, Wildwood, Philadelphia, Pa.

METAL POLISH. Will save you 50 per cent in time for making it. Decidedly the best on the market. On receipt of twenty-five cents in coin I will send sample, complete. J. Duval, Grand Junction, Colorado.

LISTS OF MANUFACTURERS.

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

INQUIRY COLUMN

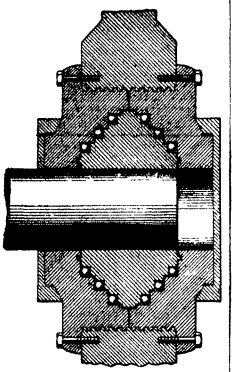
READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

Inquiry No. 9236. Wanted addresses of parties having Phonographs repaired, if able to help one.

Inquiry No. 9237. Wanted addresses of firms selling second-hand theater furniture.

Inquiry No. 9238. Wanted addresses of parties having new machinery for sale in any part of the world.



Inquiry No. 9239. Wanted name of party who is reported to be manufacturing a machine for [illegible] the position of a [illegible].

Inquiry No. 9240. Wanted addresses of parties able to sell [illegible] machinery.

Inquiry No. 9241. Wanted addresses of manufacturers of [illegible] cement, cement or other materials suitable to use therefor.

which the travelers will be held in proper position for dispensing, and supplied to the device in such position. With the improved binding wire, the travelers may be placed on the magazine in proper position for dispensing, and they cannot become disarranged during transfer, neither can they be lost from the wire, if the pins are retained in place, until the binding wire is centered.

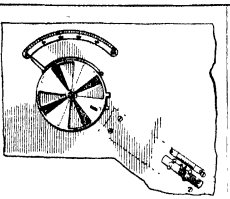
ROLLER BEARING.—LUTHER BADGER, St. Johns, Ore. This roller bearing is designed for general purposes, as, for example, car, locomotive, automobile and other vehicle wheels, and also machines of various characters. The invention is shown in the engraving which represents a central longitudinal section of the bearing and the improvement contemplates an anti-friction bearing capable

ROLLER BEARING

of free working under end thrust in either direction or a lateral strain as that occasioned by the weight of the load the bearing consisting of an inner and outer bearing member, and an internally threaded bearing support, the inner bearing member increasing in diameter in passing from the ends toward the center and the outer bearing member composed of two sections threaded into the bearing support from the opposite sides thereof.

Hardware and Tools.

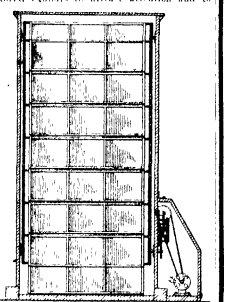
WRENCH.—CHARLES KANE, National Military Home, Tenn. This wrench is provided with different sized jaws, any one of which can be readily moved into active position and securely locked thereto. Use is made of a jaw head mounted to turn on the end of the wrench handle and having a plurality of integral jaws of different sizes and a bolt slidable lengthwise on the handle and



WRENCH

having its outer end reduced in step form to engage and fit any one of the jaws, to hold the jaw head against turning in either direction on the handle. The engraving shows a plan view of the wrench having two jaw heads. It is all steel and durable, the jaws and locking bars are tempered cold steel and contain neither rivets nor threaded screws in the locking parts. The revolving jaws respond readily to the movement of the push button, and the angle at which the head locks, enables an operator to reach nuts or bolt heads in narrow and intricate spaces.

Heating and Lighting.

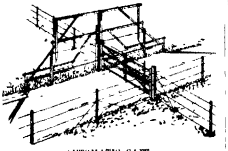


OVEN THERMOMETER AND VENTILATOR.—HENRY C. FRANKENBERG, Bonners Ferry, Idaho. This device will automatically regulate the draft of an oven, whereby to maintain a predetermined temperature, will indicate the temperature and may be regulated to operate at different temperatures. The engraving shows a front view of a portion of the oven, with the improvement in place. Superposed strips and damper are so arranged that between certain predetermined temperatures, the damper is not affected. When, however, heat exceeds predetermined high temperature, the damper is closed, the composite bar being flexed toward the lamina having the lowest coefficient of expansion. As soon as the damper is closed, temperature rises, and the damper again gradually opens and is held open until the high temperature falls. When the damper is open or closed, some little variation in temperature is permitted before the damper operating mechanism again comes into play.

OVEN THERMOMETER AND VENTILATOR

Machines and Mechanical Devices.

PICTURE DISPLAY CABINET.—MARK C. PHILLIPS, State Agricultural College, Corvallis, Ore. Among the principal objects which this invention has in view are: To provide an automatic mechanism to expose successively pictorial exhibits to attract attention and to



PICTURE DISPLAY CABINET

please passers by, and to provide a flashlight mechanism for periodically illuminating the said exhibits. The illustration shows a vertical longitudinal section of a machine which in operation gives an attractive and continuously uninterrupted display of pictorial designs interspersed with entertaining advertising matter.

RAZOR STROPPING MACHINE.—A. TOMANDER, New York, N. Y. This machine may be operated alternately by motor or manual power. The blade is addressed in approved position to the stropping members, the blade is oscillated to present opposite sides thereof to the stropping members, the stropping device has a continuously moving double belt adapted to receive therebetween the blade to be stropped, the double and face buffed stropping member is arranged to receive between the faces thereof the blade to be stropped, the device holds the blade in inclined position when stropped, and means provide for varying the belt tension.

AUTOMATIC GATE.—LOUIS A. LAAS, Maxwell, Texas. This invention relates to automatic gates and more particularly to gates that are unlatched and opened by a vehicle approaching along the road and closed and latched again through the same agency, all of which is done automatically. An object is to avoid entanglement between the swinging gate

AUTOMATIC GATE

itself with many or heavy operating parts. The gates is shown in the accompanying engraving, which pictures the various features of the construction, among which is the provision at each side of the swinging gate of separate vehicle-engaged road members, preferably in the nature of fulcrumed running boards, and located at opposite sides of the road, one of which controls the opening and the other the closing of the gate.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

Select Your Speed Indicator FIRST—

TO have a Warner Auto-Meter on your car is more important to you than the top, the glass front, or any other accessory. It's almost as important as *the car itself*. This statement may at first seem overdrawn—but

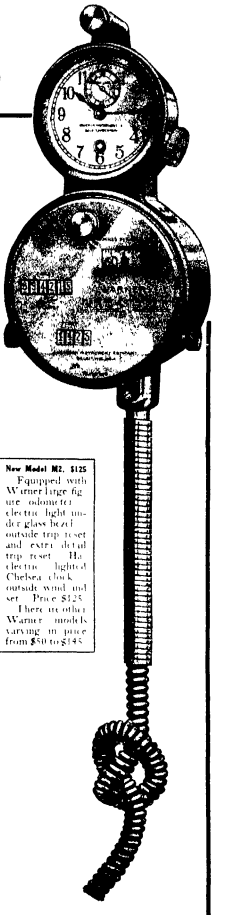
Consider These Points—

No matter what top or glass front you select, you cannot go far wrong—all are good. *There is no definite standard of value.* The *Warner* is recognized as the Standard of Speed Indicator Values because of its Supreme Quality and enduring accuracy. You can go *away wrong* if you select the wrong Speed Indicator, for not all are good.

* * *

The Speed Indicator is the most-looked-at thing on an automobile. The driver refers to it constantly every instant the car is in motion.

Other car owners and those who pass your car when drawn up at the curb, *look for the Speed Indicator* when deciding for themselves or for others whether you are driving a good car or not.



It is common knowledge among Motorists and Laymen that the Warner is the *Highest-Quality* Speed Indicator and that it is used on the *best cars*.

Therefore, if the car carries a Warner on the dash, they unhesitatingly brand that car as *Good*. If it is an inferior and unreliable Speed Indicator, the Quality of the car is open to suspicion in their minds. Our Branch Managers and Salesmen in every important city report having many times heard people on the sidewalk, who have stopped beside a car, say in almost the same words:

"I do not see the name of the car, but it *must be a good one* for it has a Warner Auto-Meter on it."

* * *

We are stating facts when we say that the Quality *Warner* is accepted by the General Public as a *reliable index* of the *Quality* of the *car* which carries it on the dash.

New Model M2. $125

Equipped with Warner large figure odometer, electric light under glass bezel outside trip reset and extra detail trip reset. Has electric lighted Chelsea clock outside wind and set. Price $125. There are other Warner models, carying in price from $50 to $145.

WARNER
AUTO-METER

"The Aristocrat of Speed Indicators"

The Warner can be secured through reputable Automobile dealers in any city or town in the United States. Warner branches are maintained in all the principal cities for the convenience of these dealers and their customers. Inquiry to Beloit or at our branches is invited for Warner literature.

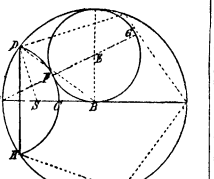
Velvet
THE SMOOTHEST TOBACCO

Do you realize what a "smooth" tobacco really is? One that can't bite? If not, try Velvet. It means cool smoking. And, it means a whole volume of enjoyment besides—a rich, mellow fragrance that is peculiar to the carefully selected and carefully matured Burley leaves. Try it today and you'll never be content with other tobaccos.

At your dealer's, or if he is sold out, we'll send you a can for a dime to any address in the U. S. A.

SPAULDING & MERRICK
Dept. 7. Chicago, Ill.



Notes and Queries

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full blasts to correspondents are printed from time to time and will be mailed on request.

(12493) A E S asks: 1. Can you inform your subscribers the degree of coefficient of expansion and the malleability of copper, brass, aluminium, soft iron, and steel? A. The coefficients of linear expansion for the metals you name are per degree Fahrenheit, and at a temperature of 104 deg Fahrenheit, as follows: Copper, 0.00000810; brass, cast, 0.00001041; brass wire, 0.00001072; aluminium, 0.00001285; soft iron, 0.00000672; annealed steel, 0.00000907. No figures regarding malleability are reliable unless the condition of the sample is carefully determined. The general order of the pure metals in malleability, as known, is: Easiest is gold, silver, aluminium, copper, tin, lead, zinc, platinum, iron. 2. What is the metal or alloy having the nearest coefficient to glass? A. Platinum is the only metal which has the same coefficient of expansion as glass.

(12494) A. W. K asks: Has anyone any experimental knowledge of a substance which, if shaped like a wedge, will weigh more when lying on its side than when lying on its back with the edge up? The writer firmly believes this to be possible, and that the heaviest substance is most likely to exhibit this phenomenon. A. We can answer your question that a wedge will weigh less when standing upon its head than when lying on its face, since in the former position its center of gravity is farther from the center of the earth than when it is on its face. It would require most delicate balances to show this in any piece of metal which such balances can weigh correctly.

(12495) F R S says: I was interested in a method given in query 12456 for inscribing a hexagon in a circle, and hereby submit a geometrical solution for same. It is only a combination of two problems in the ordinary text books. I thought the solution might be of interest to your readers.

A Theorem: Line HB, as side of inscribed pentagon. Proof: First, to prove that AC is a mean ratio between AB and BC or

$$AB : AC :: AC : CB$$

$$AB = AE - EB$$
$$AB^2 = (AE - EB)^2$$
$$= (AF + FE)^2 - EB^2$$
$$= (AF + EB)^2 - \overline{EB}^2$$
$$= \overline{AF}^2 + 2AF \times EB$$
$$= AF(AF + 2EB)$$
$$AC(AF + FC)$$
$$AC(AC + AB \text{ since}$$
$$BE = \frac{AB}{2} \text{ (construction)}$$
$$= \overline{AC}^2 + AC \times AB$$
$$AB^2 - AC \times AB = \overline{AC}^2$$
$$AB(AB - AC) = \overline{AC}^2$$
$$AB : AC :: AC : CB \text{ or}$$
$$\frac{AB}{AC} = \frac{AC}{CB} \therefore AB : AC :: AC : CB$$

Make $AS = CB$, $BB = AC$

Now, from above: $= AB, BS :: BS : AS$ by construction and $AD = AC$ by construction. AB AD : AD AS, hence $\triangle BAD$ and SDA are *similar*, but $\triangle BAD$ is isosceles, $\therefore SDA$ is isosceles and $AD : DS :: AC : SDB$ is isosceles and $\angle DBA = \angle ADS$, but $\angle DSA = \angle DBA + BDB = 2DBA$. Hence $\angle DSA = 2DBA$. Sum $\angle s$ of $\triangle DBE = 5 \times \angle ABD = 5$rt $\angle$s and $\angle ABD = \frac{1}{5}$ of 5rt $\angle$s or $\frac{1}{5}$ of 4rt $\angle$s. Hence AD = $\frac{1}{5}$ of a circumference *or arc DAH is $\frac{1}{5}$ of a circumference!* Q. E. D

(12496) G O B says: Your answer to query No. 12467 in your June 10th issue interested me greatly. I want to ask: 1. If the rise in temperature of air during compression is due to the more rapid collisions of the molecules? A. The compression of a gas is the effect of a mechanical force against the outward pressure due to the heat energy of the gas, which varies with its temperature. The result of the compression is to bring the molecules nearer together and produce more collisions per second by reducing the mean free path through which a molecule can move before it collides with another molecule. The outward pressure is increased, and the collisions are both more numerous and more violent. The temperature is raised for both reasons. 2. What is the cause of the drop in temperature upon the air being released from pressure? A. The opposite action, namely, expansion, produces the opposite effect, namely, a drop in temperature. The distances between molecules are increased, the mean free path is lengthened, and the number of collisions is reduced.

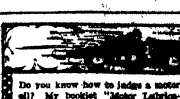
(12497) O W E asks: Would you kindly tell me where I could get some information regarding "colloidal solutions," or a finely divided metal in a liquid? I am particularly interested in copper. If you have any SUPPLEMENTS containing anything on this subject, kindly tell me what they are. A. You will find valuable articles upon colloidal solutions in the SUPPLEMENT Nos. 1477, 1581, 1779, 1804, price ten cents each. The subject is treated in all the physical chemistries. We can send you Jones's "Physical Chemistry" for $4, also Zsigmondy's "Colloids and the Ultramicroscope," price $3.

(12498) J. S. R. asks: 1. I would like to know if there is any substance of any kind that smoke will dissolve or act on in any way. A Smoke is a mixture, differing with the fuel which is burned, and with the incompleteness of the combustion. The black portion which we usually call the smoke is simply the unconsumed carbon drifting away. This cannot dissolve anything. The gases from the combustion are able to act upon many materials and corrode them. There is also much hot-water vapor in smoke, which becomes water when it is cooled and aids the rusting of iron or corrosion of other metals upon which it may be condensed. 2. Is mercury a conductor of electricity, or anything in liquid form that is? A. Mercury is a conductor of electricity, as also are all solutions of metallic salts such as copper sulphate and common table salt, and most acids mixed with water. There are thus a great many liquid conductors.

(12499) H O. S says: Regarding the sounds given forth by the reproducer of a talking machine, the manager of the record department of one of the principal companies asserts that during a band selection all the instruments playing at one instant are given forth by the producer at one instant or at the same time. Now will you kindly answer this: Is it not a fact that any object giving forth different tones by vibration can have but one rate of vibration with its accompanying tone at any one instant or fraction of a second it being impossible for it to vibrate at two different rates at the same instant? I have always understood and believed this to be so, and it seems to me to disprove the record department manager's assertion. Taking the length of the record groove passed over by the reproducer during one second my opinion is that there is but one sound at any one time, as there is one sound each smallest fraction of the second and they follow each other so swiftly, the ear cannot comprehend that it is being deceived, and believes it hears more than one instrument at the same time. Could not this be positively ascertained by having two trombones or cornets play each a different sustained note, and see if the reproducer would give the two tones together or two different notes on an organ would be more mechanically exact and even. A. It is not a fact that any object giving forth different tones by vibration can have but one rate of vibration with its accompanying tone at any one instant or fraction of a second. It is very possible for it to vibrate at two different rates at the same time. The difference in tone quality of different musical instruments is due to this very fact, and a vibrating string of piano or violin vibrates at a large number of rates at the same time. The recorder of a talking machine takes a form of motion due to the resultant of all the forms of motion which it receives from the sounding instruments, and for this reason the record can impress upon the reproducer the same tones as it has received from the motion of the recorder. Doppler's Principle is the accepted explanation of this fact. Many tracings of combined tones have been made. It is of course very difficult, if not impossible, to extend such records to the very complicated results of the impressed curve of the disk of a talking machine for an orchestra, but the fact that this is true of simpler compositions of tone leads with certainty to the belief that it is also true of the complex tones of the band or orchestra. We do not look for any change in the accepted theory on the matter. The opinion of the manager of the record department which you quote is entirely in accord with our own.

(12500) J. W. N. asks: Under the rules of science, as taught by the institutions of the world, is it possible for any man or agency to forecast the weather for months

Do you know how to judge a motor oil? My booklet "Motor Lubrication" will help you. It tells of the perfect lubricating qualities of



Panhard Oil
For Motors—

But it is more than an ordinary advertisement. I will send it free if you will give the name of your dealer.

Don't merely ask for good oil—say "Panhard," because:

It is refined from the finest oil in the world. Pennsylvania crude. Abundantly sufficient in quality. Will not carbonize if properly used. Not evaporate. Will not foul the motor. Will not corrode valves, pistons, rings or cylinder body. Lubricates always at high or normal temperature. Sold in "Checkerboard" cans or in barrels. 30 years of Oil Experience has taught us how to offer Lubrication "—and this is for you—if you write to-day.

ground, as is done by a few self-annointed prophets and so-called weather bureaus of this country? A. It is not possible to foretell the weather for any extended period, beyond the most general terms. The U. S. Weather Bureau after years than forty years of continuous practice does not attempt specific predictions for more than thirty-six hours. Long-range forecasting is not yet reliable. The conditions which determine the motions of the vast masses of the atmosphere are too little known. When a storm appears in our western region, it is not possible to tell at what point it will leave the Atlantic coast, or what its path will be across the country. The success of the U. S. Weather Bureau in forecasting storms, frosts, and river floods is very remarkable, and this work of the Bureau is worth many times its cost, but those men are very careful to disclaim the ability to predict the weather for any specified place for any extended period.

NEW BOOKS, ETC.

THE SHIPPING WORLD YEAR BOOK. A Desk Manual in Trade, Commerce, and Navigation. Edited by Evan Rowland Jones. London: The Shipping World Offices, 1911. 8vo.; 1765 pp.

The twenty-fifth edition of this well-known annual is bigger and better than ever before. Scarcely anything of importance within its scope has been omitted. The new tariffs of Austria-Hungary, Bulgaria, France, Japan, The Netherlands, Sweden, and Greece are given. There is a complete port and harbor directory of the British Isles and a directory of all the commercial ports of the world, with particulars as to accommodations, charges, tides, trades, pilotage and towage, revised up to the hour of printing. Among new features of the edition may be mentioned the tables of freeboard, a digest of the merchant shipping Acts from 1894 to 1909, tables of foreign money, weights and measures, with English equivalents, foreign trade statistics for 1910, details of the world's shipbuilding output for the past year, and a mass of invaluable information which the exhaustive index makes easily available. A new map of the world, especially prepared by J. G. Bartholomew, F. R. G. S., folds into a pocket at the back of the volume. This shows the routes of steamers and railways throughout the world, and the products, ports, coaling stations and coal fields of all countries.

ARGENTINA AND HER PEOPLE OF TO-DAY. By Nevin O. Winter. Boston L. C. Page & Co., 1911 8vo.; 421 pp.; Illustrated. Price, $3.

Argentina, like the other countries of South America, has received far less consideration than it is entitled to. One of the greatest food-producing countries of the globe, queen of the South American republics, first among them all in import and export trade, with a capital ranking as one of the greatest cities of the world, Argentina must quicken the pulse of all who are attracted by the new, the progressive, the resourceful, and the ambitious. We have in the volume before us, to use the author's own designation, "an account of the customs, characteristics, amusements, history and advancement of the Argentinians, and the development and resources of their country." It is a brightly-written and well-made volume enriched by charming views and illustrations.

NORTH DEVON WITH WEST SOMERSET. By Beatrice and Gordon Home. New York: Frederick Warne & Co. 12mo; 230 pp; illustrated.

This is a little volume to fit the pocket, containing some very good views of the countryside, coast scenery, and picturesque buildings. The part of England with which it deals has an exceptional and distinctive beauty, as everyone knows. Such names as Covelly, Ilfracombe, and Exmoor conjure up pictures of appealing quaintness, glimpses of rugged promontories and far-flung bays lying in purplish light, and stretches of wild moor and wild-blown spaces. We are now in the land of Lorna Doone and her "girt Jan Ridd." The book is not a stereotyped guide, although its large-scale maps slight nothing, but is almost like a gift-book in style and make-up—would, indeed, admirably serve that purpose—and is full of sympathetic description and discriminating illustration.

HOMESTEAD. The Households of a Mill Town. By Margaret F. Byington. New York: Charities Publication Committee, 1910. 8vo.; 262 pp. Price, $1.50; postage, 30 cents.

Homestead is a town. Homestead is also the mill which perpetuates the town. But Margaret Byington's book is mainly of the home life the mill town lends on the wages which the mill pays. It is a community of working men, representing an early Teutonic-Celtic wave of immigration and a later Slavic influx. Perhaps the main interest of the survey centers on "life at $1.65 a day." We are set so much drawn to a study of middle-class living and hundreds respectability. Our literature must give us either the prince or the pauper—either Brewster's millions or the widow's mite. These nine-dollars-a-week men with wives and families can allow themselves just twenty-two cents per man for a day's food. The Committee on Trade and Commerce estimated that in Pittsburgh a liberal provision of food for a family of five could not be purchased for less than $11 88 per week. From these contrasting figures we may draw our own conclusions as to the unenviable state of the unskilled worker in the steel mills. Rents are high. The twelve-hour day, continued in many cases through the seven days of the week, leaves no time for anything else save food, a pipeful of consolation, and sleep. This is of course the shadow of the picture, there are higher lights. The volume is one of the six which comprise the notable Pittsburgh Survey findings, and is remarkable for the way in which it goes to the very heart of things and tabulates human strivings, longings, and limitations in columns of cold type.

THE CHEMISTRY OF THE COAL TAR DYES. By Irving W. Fay, Ph.D. New York: D. Van Nostrand Company, 1911. 407 pp. Price, $4 net.

The book gives a good presentation in concise form of the principal classes of organic dyestuffs. An idea of its contents and their arrangement may be obtained from the chapter headings, which are as follows: 1 Introduction, 2, Coal Tar and Its Products, 3 and 4 The Hydrocarbons and their Derivatives 5 The Nitro and Nitroso Dyes 6 The Triphenylmethane Dyes 7 The Classification of the Coal-Tar Dyes 8 The Azo Dyes 9 The Seven Food Colors (Devoted to the seven dyes whose use in foods and beverages has been sanctioned by the U. S. Government) 10 The Pyronines 11. The Indamines, Indophenols, Thiazines, Oxazines 12 The Eurhodines and Safranines 13 The Quinoxaline, Quinoline, and Acridine Dyes. 14 Aniline Black 15. The Alizarine Dyestuffs. 16 Indigo. 17 The Sulphur Dyes 18 Mordants 19 Experimental Work. In point of publisher's technique the book deserves the highest praise, and there is a wealth of fully tried out structural formulæ. The treatment of the subject leaves nothing to be desired. A number of new prints an an occasional roughness in literary style should be eliminated by tension in a later edition. A curious omission occurs in the index, which, under the entry "Indigo," fails to give the most important reference, namely, that to the chapter on Indigo on page 375. The last portion of the book, pages 417 to 458, forms a laboratory guide for the preparation of some of the typical dyestuffs.

DICTIONARY OF ENGLISH AND SPANISH TECHNICAL AND COMMERCIAL TERMS. By William Jackson. New York: Spon & Chamberlain, 1911. 12mo, 164 pp. Price, $1.

An excellent idea is embodied in this neat little glossary, for it concerns itself with listing and interpreting the special terms of the iron, steel hardware, and engineering trades for the benefit of those who are engaged in ordering or in filling orders for these products between English speaking and Spanish speaking countries. As it is impossible to find many such technical names in the ordinary dictionary, this compilation should promote ease of commercial intercourse and find favor with a large class of buyers and shippers here and abroad. Between three and four thousand words and phrases are alphabetically listed.

HOW TO MAKE A WIRELESS SET. By Arthur Moore. Chicago: Popular Mechanics Company, 1911. 12mo; 84 pp., Illustrated. Price, 25 cents.

Boys all over the country are dabbling in "wireless," and many more will take up the hobby when they find how easily a short-distance outfit may be constructed. The instructions here given are for the making of a set that will transmit to a distance of four or five miles.

HOW TO LIVE IN THE COUNTRY. By E. P. Powell. New York: Outing Publishing Company, 1911. 8vo., 300 pp.; Illustrated. Price, $1.75 net.

Mr. Powell is well known as a prolific and sympathetic writer on rural subjects. He speaks from the fulness of an appreciative personal experience, and in this instance tells us how a large life may be lived on a small acreage. Both the dweller in the country and the city man who dreams of farm life may gain strength and breadth of outlook from the author's practical wisdom and inspiring description. The work is primarily a guide to choosing and making the most of a country home. The chapter entitled "Can we make it pay?" touches upon what is to most of us the vital point, and never while it encourages,

THE BOOK OF ROSES. By Louis Durand. New York: John Lane Company, 1911. 8vo.; 101 pp. Price, $1 net; postage, 8 cents.

The rose is everybody's favorite, symbolical of all the beauty and fragrance of life. Almost any soil can be made to grow roses of one kind or another. The various soils and their preparation forms the theme of the first two chapters. The question of planting is argued, and budding, sowing, and striking as methods of propagation are examined with thoroughness. Much space is given to describing the varieties—wild, autumn-blooming, decorative, and climbing roses. The full-page plates will delight the heart of the flower lover, for they seem almost to exhale the perfume of the specimens they picture.

The ambition of every tiremaker in the world is to some day make a non-skid tire as good, and as popular as the famous

NOBBY TREAD

Eighteen months ago, Nobby Treads were first placed on the market. Since then they have been sweeping the country, replacing every form of non-skid tire or non skid device on cars in every state in the Union, and in every possible kind of service.

Skidding Protection—These big thick diagonally placed knobs grip the slipperiest road or pavement at every possible angle. They hold the wheel against skidding and drive slipping even on a wet asphalt pavement.

They reach down deep into muddy or sandy roads and hold the wheel secure where a plain tread would spin around unhindered.

Wearing Quality—In decided contrast to the ordinary so-called non skid tires those tough rubber knobs expose no large surface to the wear and tear of the road that it takes thousands of miles of the hardest kind of service to wear them smooth. When they finally do wear down a plain tread still remains good for many more miles of service.

For safety's sake for economy's sake equip your car with "Nobbies"

A Comparison of the German and American Navies

(Continued from page 78)

9¾, and ours from 9 to 12 inches—all Krupp armor. The upper sides of all these ships are protected by plates averaging 7 inches in thickness. But the American ships mount main batteries of modern 12-inch guns against the greatly inferior 11-inch weapon in the Teutons. The eight "Connecticuts" have each a broadside of four 12-inch 45-caliber rifles, which, as we have said, will send a shell through any plates the Germans carry, while the latter's 11-inch 40-caliber weapons are useless against more than 6-inch armor at 8,000 yards. And every one of the five "Georgias" and three "Maines" mounts four 40-caliber 12's which are effective at 8,000 yards against plates 8¾ inches thick.

The remaining ten "Wittelsbachs" and the older Americans are probably of too little offensive value to be seriously considered except for a second line of offense.

Certain it is, however, that the old 9.4's of the "Wittelsbachs" would be absolutely useless at ranges where the 13's of the "Alabamas," "Kearsarges" and "Indianas" could work fearful havoc with their 1,100-pound shells. The superior speed of the German vessels might indeed enable them to close in upon the Yankees, so as to give their guns a chance, but they would be fearfully punished before they could hope to even mat-

This diagram shows that the batteries of United States ships have far greater penetrative power than those of the German ships.

ters up in that way.

We have hitherto taken no account of the secondary batteries, because so great is the skill to which gun pointers have attained in recent years that it is doubtful if battleships would fight at ranges at which the lighter guns would be greatly destructive. It is true that they could even at a distance inflict much harm on the unarmored portions of the hull (fore and aft) and upper works, but almost all the complement of a modern battleship are stationed behind armor, and furthermore, the high trajectory of the 8's, 7's and 6's makes it more difficult to hit with them than with the larger pieces.

Armored Cruisers.

When it comes to armored cruisers the navies are more evenly matched. The splendid "Von der Tann" finds no counterpart on our list, more's the pity, and even the "Blucher" has some advantages over our "Montanas"—as in the matter of speed for example. But the rest of the Germans are a sorry lot, and our own "West Virginias" are not much better. As for the three "Charlestons"—they are hardly worth mentioning, being utterly useless from an offensive point of view.

In the matter of torpedo-boat destroyers, the Germans are much better off than we are. They have ninety-six of these ready for sea, ranging from the latest models of 620 tons and 34 knots speed to old and slow (25-knot) craft of 400 tons. We possess sixteen 400-tonners of 25 knots speed and twenty brand-new boats of 700 to 750 tons and upward of 31 knots speed.

On the other hand, the American navy has some twenty-six submarines to the German navy's eight; but this kind of craft is more especially adapted to the work of coast defense, and therefore need not be taken into consideration to any great extent.

In fast protected cruisers and gunboats the German navy has a considerable superiority over our own, but however useful the former may be as scouts for the fleet they cannot have any actual value in battle. Therefore we have left them out of our consideration of the relative strength of the two navies.

A summary of broadsides (for modern strategy points to the universal adoption of broadside firing in actions between fleets) of the various groups of battleships, as in the accompanying table, will show at a glance the immense superiority of the American ships in the ability to deal telling blows.

Herewith is given in graphic form a diagram showing the overwhelming superiority of the American battle fleet in the matter of heavy guns, 68, or exactly half of the total, being 12-inch rifles capable of successfully attacking at 8,000 yards the heaviest armor worn by the Germans. On the other hand, not a single one of the Kaiser's ships could at that distance pierce the main belt of any of the Americans, and only 32 of the newest rifles (11-inch, 45 caliber) would be effective against the Yankee topsides.

In time of stress it is the armored ships that count, and the tables given above demonstrate beyond peradventure of a doubt the present offensive superiority of the United States fleet.

Germany is contemplating equipping her newest dreadnoughts with ordnance of 12 2-inch caliber, but these undoubtedly powerful weapons will be more than compensated for by the new 14-inch rifles which are to be mounted in our "Texas" class, recently laid down. All this, however, is beside the question, as our object has been to demonstrate that at the middle of the year 1911, the German navy, far from being a menace, is not by any means the equal, offensively, of the fleet that flies the Stars and Stripes.

Heart Diagnosis by Electricity

(Continued from page 81)

the main circuit. This gives the various "derivations" or "leads" (1) Right arm and left arm, (2) right arm and left foot, (3) left arm and left foot. The wire from the left foot always goes into the same main wire and the left electrode occupies the same position in the circuit as the right arm does, otherwise an inverted electrocardiogram will be obtained. It is necessary to attend to these details, because some diseased conditions cause an inverted electrocardiogram. From the switches the two main wires lead to the galvanometer. In most instances when the patient is connected to the galvanometer, there is a large permanent difference of potential between the two parts of the body (so-called body-current) where the electrodes are attached. This deflects the fiber far to one side, and must be compensated. A commutator is placed in the circuit which serves the purpose of connecting in and sending in either direction around the main circuit a current from a battery (reduced to sufficient strength by a resistance coil). This is sent in the opposite direction to the "body-current," and serves to neutralize the primary body potential, and to effect what is called "compensation of the zero-current."

For making phonocardiograms simultaneously with electrocardiograms, the microphone is wired to a smaller galvanometer. The wiring of the microphone is simple. It is connected with a dry battery in a circuit with the primary of an induction coil. Wires from the secondary lead to the junction points of the wires from the galvanometer and resistance coil. The constant battery current passing through the primary induces no current in the secondary. Changes, however, in the strength of this primary current as the result of sound vibrations on the

Valuable Books

The Scientific American Cyclopedia of Formulas
Edited by ALBERT A. HOPKINS. Octavo, 1077 pages, 15,000 Receipts. Cloth, $5.00; half morocco, $6.50.

¶ This valuable work is a careful compilation of about 15,000 selected formulas, covering nearly every branch of the useful arts and industries. Never before has such a large collection of valuable formulas, useful to everyone, been offered to the public. Those engaged in any branch of industry will probably find in the volume much that is of practical use in their respective callings. Those in search of suitable articles which can be manufactured on a small scale will find hundreds of most excellent suggestions. It should have a place in every laboratory, factory and home.

Handy Man's Workshop and Laboratory
Compiled and edited by A. RUSSELL BOND. 12mo., 467 pages, 370 illustrations. Price, $2.00.

¶ This is a compilation of hundreds of valuable suggestions and practical ideas for the mechanic and those mechanically inclined, and tells how all kinds of jobs can be done with home-made tools and appliances. The suggestions are practical, and the solutions to which they refer are of popular occurrence. It may be regarded as the latest compilation of ideas of practical men published, and appeals to all those who find use for tools either in the home or workshop. The book is fully illustrated, in many cases with working drawings, which show clearly how the work is done.

Concrete Pottery and Garden Furniture
By RALPH C. DAVISON. 16mo., 196 pages, 140 illustrations. Price, $1.50

¶ This book describes in detail in a most practical manner the various methods of making concrete for ornamental and useful purposes. It tells how to make all kinds of concrete vases, ornamental flower pots, concrete pedestals, concrete benches, concrete fence, etc. Full practical instructions are given for constructing and finishing the different kinds of molds, making the wire forms or frames, selecting and mixing the ingredients, covering the wire frames, modeling the cement mortar into form, and casting and finishing the various objects. With the information given in this book, any handy man or novice can make many useful and ornamental objects to ornament the adornment of the home or garden. The information on color work alone is worth many times the cost of the book.

The Design and Construction of Induction Coils
By A. FREDERICK COLLINS. Octavo, 295 pages, 159 illustrations. Price, $3.00.

¶ The work gives in minute detail full practical directions for making eight different sizes of coils, varying from a small one giving a one-half-inch spark to a large one giving twelve-inch sparks. The dimensions of each and every part down to the smallest screw are given, and the directions are written in language easily comprehended. Much of the matter in this book has never before been published as, for instance, the vacuum dryers and impregnating apparatus for the wax, the paraffine wax condensers, the construction of interlocking reversing switches, the set of condensers using diagrams, etc. The illustrations have all been made from original drawings, which were made especially for the work.

Industrial Alcohol Its Manufacture and Uses
By JOHN K. BRACHVOGEL, M.E. Octavo, 328 pages, 107 illustrations. Price, $4.00

¶ This is a practical treatise, based on Dr. Max Maercker's "Introduction to Distillation" as revised by Dr. Alexander and Lange. It contains raw materials, malting, mashing and yeast preparation, fermentation, distillation, denaturing and purification of alcohol, alcoholometry, the value and significance of a tax-free alcohol, methods of denaturing, its utilization for light, heat and power, production, and a statistical review and the United States law. This is one of the most authoritative books issued on the subject and is based upon the researches and writings of the most eminent of Germany's specialists in the science of fermentation and distillation. It covers the manufacture of alcohol from all raw material in the most modern and purified product, including chapters on denaturing, domestic and commercial utilization.

Any of these books will be sent, postpaid, on receipt of advertised price

microphone, set up induced currents in the secondary, and these are recorded by the galvanometer.

In healthy people the electrocardiogram assumes, in the majority of instances, a certain typical form. The term "typical" or "schematic" is used instead of "normal," since slight deviations from it may occur in people with normal hearts. When any muscle is excited to contract, the active portion is always electrically negative to the part at rest. This is true, therefore, in the heart, and electrical changes show the course of excitation. The curve for each heart period presents throughout three principal waves upward, indicating an electrical negativity of the base of the heart with regard to the apex at three different instants in a single cardiac cycle. These three elevations have been designated by Einthoven as *P, R,* and *T*. The curve presents, also, in many instances, two slight excursions or waves downward, depressions, indicating a negativity of the apex of the heart with regard to the base at two different instants in each cardiac cycle. These two depressions, though less constantly present than the three elevations, have been designated by Einthoven as *Q* and *S*.

By the course and height of these waves, as shown in the records, the physician can tell by eye whether the heart undergoes normal electrical changes or abnormal, in the latter instance an analysis of the abnormal appearances of the record throws light upon the disease of the heart-muscle which is present.

The two accompanying illustrations will give a clearer conception of the method of observation. The upper of the two diagrams is an electrocardiogram. The lower is a diagram, on an enlarged scale, of a section of the electrocardiogram, which will make plainer the changes in a single cardiac cycle. Waves with the apex upward indicate that the base of the heart or the right ventricle is negative to the apex or left ventricle, and is therefore excited at that time. Waves with the apex downward have an opposite significance. Wave *P* is due to the excitation of the atrium (or auricle). Waves *Q, R, S* and *T* occur during the excitation of the various portions of the ventricle.

What this instrumental investigation signifies not only for the discovery of disease, but also for diagnosing its precise character, it is as yet too early adequately to judge but many physiologists and physicians believe that it will prove to be a very valuable aid to the medical profession. While the galvanometer, the photographic recorder and the auxiliary instruments have in this country already furnished data of importance in connection with animals as well as human beings, the work in Europe has been far more extensive, as a larger number of stations have been established.

Light-producing Bacteria and Fireflies

A FEW years ago Prof. Molisch determined that of all the light-producing bacteria *Pseudomonas lucifera* produced the brighest light. F. Alexander McDermott presented before the Biological Society of Washington the results of his own further experiments with this organism. A culture of these bacteria was sent to Washington by Prof. Molisch, so that the form used was identical with the original material.

Mr. McDermott finds that the bacteria will grow in gelatin or a liquid medium, doing better however in gelatin; in all cases it needs the presence of from 2.5 to 3 per cent of common salt, or certain other mineral. A culture will continue to give off light actively for about a week, reaching the maximum 48 hours after inoculation. The light is a soft green of "considerable intensity." The following formula furnished the best culture medium: Peptone, 1 per cent, Asparagin, 1 per cent, Magnesium chloride 0.5 per cent, Sodium chloride 2.5 per cent, Glycerine 0.5 per cent.

Solutions of greater concentration were not so favorable to the growth of the bacteria, and Mr. McDermott suggests that the organism is "apparently sensitive to overfeeding." It is perhaps simply an indication, however, of the osmotic limits of the minute cell.

The spectrum of the light emitted runs from yellow-orange to indigo and is less constant than the light from certain fireflies, though similar in appearance to the naked eye. Although the light from cultures in a liquid medium looked whiter to the eye, the spectrum was the same.

The luminous tissue of fireflies had already been shown capable of again emitting light when moistened, after having been dried in a hydrogen vacuum - even after the lapse of from thirteen to eighteen months. It had also been found that the light was brighter when the tissue was moistened with hydrogen peroxide solution. Similar results are now reported for dried cultures of *Pseudomonas*. Oxygen under pressure also restored the luminosity.

The general character of the light produced by the firefly and by these bacteria is the same, but there is no reason to suppose that the process by which it is produced is the same in the two cases. But it is probable that the luminosity is connected with oxidation in both organisms.

The Current Supplement

THE opening article of the current SUPPLEMENT, No. 1855, deals with the Grand Trunk Transcontinental Canadian Railway.—Major George O. Squier's paper on Multiplex Telephony and Telegraphy is continued.—The heat-insulating efficiency of vacuum-jacketed bottles is discussed by A. A. Somerville.—Command ant Renard's paper on "What Constitutes Superiority in Airships" is concluded.—Before the Society of German Marine Engineers the contributions of Goethe to science and industry are considered.—Jacques Boyer writes on the application of the Dussaud principle of illumination to moving picture projection.—The Berlin correspondent of the SCIENTIFIC AMERICAN describes an apparatus for recording loss in weight.—The possibilities of aeroplanes in naval warfare are discussed by a German naval officer.—Illustrated descriptions of automobile novelties are presented.—Ralph C. Davison writes on the enormous discharge of dynamite rendered necessary in the construction of the new cut-off of the Delaware, Lackawanna and Western Railroad near Andover, New Jersey.—A good article on toxicology is contributed by Professor Levin, of the University of Berlin.

The Secret of the Maple

IT is probable that every observant person who has visited a maple grove in the early spring, while snow banks are yet lingering in sheltered hollows, and has seen pailful after pailful of sweet sap drawn from the auger-holes in the trunks, has wondered what forces govern the flow of the sap.

When the warm sun touches the treetops the flow increases. A rise of a few degrees in temperature often causes a great increase of flow, if the rise passes the zero point, on the Centigrade scale, that is, the freezing-point of water. But a considerable change of temperature in which the fluctuations do not cross the zero line causes no marked change in the flow of the sap. In the consideration of these and other related facts, the conclusion has been reached that neither expansion of gas in the wood nor expansion of water, nor expansion of the wood itself, is the underlying cause of the pressure which produces the flow, but that this pressure arises from the effects of temperature in altering the osmotic permeability of the pith-ray cells.

A New Route Across Africa.—The German Government is rapidly progressing with the railroad that is to connect Daressalam with Tabora in German East Africa. A force of 10,000 laborers is at work on the new road, of which 374 miles have been constructed. According to the *Deutsch Ostafrikanische Zeitung* the ultimate extension of this road to Ujiji, on Lake Tanganyika, is practically assured. As the Belgians have now decided to extend their upper Congo railway system to the west shore of Tanganyika, the time is not far distant when it will be possible to travel by rail, lake and river across Africa from Daressalam to the mouth of the Congo.

No-Rim-Cut Tires

10% Oversize

Six Months' Sales, 220,000

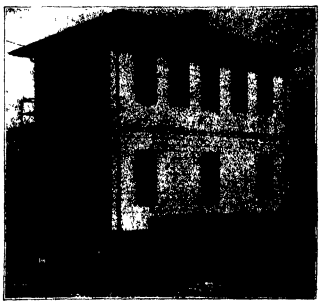
The Goodyear No-Rim-Cut tire, as most motorists know, has changed the whole tire situation. The demand has become overwhelming. It is six times as large as two years ago.

These tires cannot rim-cut. The 650,000 in use have proven that.

They are 10 per cent oversize. That means 10 per cent more air—more carrying capacity. With the average car it means 25 per cent more mileage.

Thousands have found that these two features together—No-Rim-Cut and oversize—cut tire bills in two. Yet these patented tires now cost no more than standard clincher tires. They fit any standard rim.

Our Tire Book—based on 17 years of tire making—is filled with facts you should know.



Ask us to mail it to you.

CONSERVATION

The AUGUST Magazine Number of the SCIENTIFIC AMERICAN Issue of AUGUST 12th, 1911

The next magazine number of the Scientific American, August 12th, 1911, will contain a series of articles by leading authorities, which will deal with this vital subject of the conservation of our natural resources.

Ex-Chief Forester the Hon Gifford Pinchot, whose earnest fight for the preservation of the coal lands of Alaska has led to a favorable decision of the Land Office, which greatly strengthened the cause of conservation, will open the number with an article on the Conservation of our Forests.

The Director and Chief Engineer of the Reclamation Service, F. H Newell, will write a general article on the past work and future plans of the Reclamation Service.

The Director of the Bureau of Mines, Dr. Joseph A. Holmes, will show that the waste of our supplies of coal is due not merely to careless and extravagant management in the mining of the coal, but also and very largely to methods in burning the fuel.

Dr. David T. Day, of the United States Geological Survey, will prove, in an article on the conservation of oil and gas, that, as with coal, so with oil and gas, it is possible to effect large economies by judicious management in the oil and natural gas fields and by the use of improved appliances in burning these fuels either for light or power purposes.

Dr. Hugh M Smith, Deputy Commissioner of Fisheries, will contribute an article on the Conservation of Fish, Oysters, etc., and Seals. Conservation is a word to which we are liable to give too restricted an application.

In addition to the above articles, the August 12th number will contain the usual Editorial, Aviation, and other Departments.

Electricity

Unloading Bananas by Electricity.—Fruit steamers in New Orleans and Mobile are now being unloaded by means of electric conveyors. The conveyors are provided with vertical legs that enter the hatches of the vessel. These legs support traveling chains four feet apart, which are connected by cross bars carrying canvas pockets Bunches of bananas are placed in these pockets and hauled out of the vessel The loading of the conveyor is performed from three decks, each deck filling every third bag. Each conveyor has a capacity of twenty-five hundred bunches of bananas per hour.

Avoiding Pole Lines in a Welsh Town.—In order to avoid the use of poles in the streets of a town in Wales, it was decided to run the wires on brackets supported on the sides of the buildings and the roofs The brackets are made of angle iron and extend about six feet from their support At first there was some hesitation on the part of owners about giving the right of way over and along their buildings, but this was overcome by proper precautions on the part of the company The system has proved very successful, and it avoids crowding and disfiguring the streets with poles

Outdoor Ironing.—One of the most dreaded days of the household in summer time, is ironing day Even though electric flat irons are used, the heat may become almost unbearable owing to the fact that the work is invariably done indoors. The Commonwealth Edison Company of Chicago does not see why the ironing should not be done outdoors on the porch, or in some other convenient location All that is needed is a sufficiently long conductor to connect the flat iron with a lamp socket in the house This idea has been seized upon to provide a very attractive circular showing the advantages of out door ironing and incidentally advertising the use of electricity for this branch of the house work

Electric Fans for the Sick.—According to popular impression public service corporations are organized robbers It is almost impossible to combat this prevailing idea Recently, however, the Electric Supply Company of DeKalb, Ill., has demonstrated that it can perform a work of charity in which there is no personal gain whatsoever, except for creating a better feeling on the part of the public toward it The company has notified all the physicians in the city that it will furnish electric fans and power to operate them without charge, to all patients who are unable to pay for such service and who, on the suggestion of the physician would be materially benefited by the use of fans This applies not only to such houses as are wired, but to others as well the company offering to install the necessary circuits, gratis

New Lighting Apparatus.—A very economical method of producing light by means of small incandescent lamps was shown by M Dussaud before the French Academy of Sciences He mounts 16 small lamps with one-inch bulbs around the edge of a revolving disk, provided with a set of contacts so arranged that when the disk rotates each lamp receives current for a fraction of a second. It is well known that tungsten lamps have the property of lighting up very quickly when the current is applied. He uses a 10-volt lamp and it receives 20 volts, or much more than the normal current, but for a very short time Much more light is thus given for the same amount of current Each lamp in turn passes when lighted before a fixed lens so as to project the rays, and as the lamps pass rapidly the light seems continuous His main object is to provide a suitable light for lantern projections, and he claims to secure a light equal to an arc lamp for a very small current such as a moderate-sized primary battery will give Thus it can be used where there are no current mains at hand. It is well adapted to be used as a small searchlight upon fishing boats or to be carried by soldiers, and for army use the battery can be placed in a sack upon the shoulders, together with an optical signaling outfit. Such an outfit can be used also perfectly diminishing the illuminating [illegible]

Science

Death of G. Johnstone Stoney.—Dr. G. Johnstone Stoney died recently at the age of 86. He had been astronomical assistant to the late Earl of Rosse in 1848, professor of natural philosophy in Queens University, Ireland, in 1852, and secretary of Queens University from 1857 until its dissolution in 1882. He was known chiefly for his writings on astronomy.

An Opera Glass Comet.—We have received a communication from Prof. Edward C Pickering of Harvard College Observatory, in which he states that a comet has been discovered by Kiess on July 6th in R A. 4 h 51 m. 51.8 s., Dec. 35 deg. 15 m 2 s. The comet can be seen with an opera glass, and at the time of its discovery was moving southwest and had a visible tail.

Color Photography.—A patent, 992,151, has been issued to Rodolphe Berthon of Lyon, France, for a color photography apparatus which comprises an objective with a diaphragm therein having a trichromatic screen, a sensitive surface and means interposed between the sensitive surface and the objective so that the images on the screen are separated by refraction at points in close proximity and projected in a microscopic state on the sensitive surface.

The "International Week" of Upper Air Observations.—A circular from the headquarters of the International Commission on Scientific Aeronautics announces that, owing to the fact that the attention of British as well as many foreign meteorologists will be taken up with the meeting of the British Association during the early part of September, the dates set for the "international week" of aerological observation throughout the world, in 1911, have been changed from September 5-9 to September 11-16.

A Meteorological Outpost in the South Atlantic.—An important addition to the meteorological *réseau* of the southern hemisphere was made early this year in the establishment of a meteorological station of the first order in Fernando de Noronha, a little group of islands about 194 miles northeast of Cape St Roque, on the Brazilian coast The islands are used by Brazil as a penal colony, and contain upward of two thousand in habitants Darwin has described a visit here in the "Beagle," and the "Challenger" also touched here The station is under the charge of two German employees of the Brazilian telegraph service, and sends daily telegraphic reports to Rio de Janeiro.

The Flight of Seeds.—It is popularly believed that winged seeds from trees travel to great distances on the wind, but the investigations of a British scientist, who has spent much time at Singapore, indicate that winged seeds have a far narrower range of flight than have "powder" seeds and plumed seeds The greatest distance traveled by the winged seeds of a forest tree observed by this authority was 100 yards Under the most favorable circumstances, he calculates, it would take this plant just one hundred years to spread three hundred yards, and 1,500,000 years to spread from the Malay Peninsula to the Philippines, if a land connection existed.

Illumination with Neon Tubes.—M. Ch. Ed. Guillaume recently lectured before the Astronomical Society of France on the subject of neon light. Neon, one of the rare gases of the atmosphere, is now obtained on a commercial scale in the process of making liquid air. In a vacuum tube it has several excellent qualities as an illuminant Owing to its extraordinarily feeble dielectric cohesion the voltage required is relatively small. M. Guillaume exhibited a tube six meters long, which was illuminated with a current of 1,000 volts. A light of 1,330 candle-power was produced, with an expenditure of only 850 watts, or 0.64 watt per candle-power. The light, which is of a warm golden yellow, is described as being peculiarly pleasing. The lecturer also described a process of removing from the tube traces of other gases, especially nitrogen, the presence of which [illegible]

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. Drawings or photographs of striking subjects are desired, and the facts stated in the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately and in simple terms, the world's progress in scientific knowledge and industrial achievement. It seeks to present this information in a form so readable and readily understood, as to set forth and emphasize the inherent charm and fascination of science.

Good Roads That Are Permanent

CHIEF among the qualities of a good road is that of durability, and durability can be assured only by first-class work in construction and by ceaseless vigilance in maintaining the road in perfect condition. It goes without saying that the highways of America, considered as a whole, are not to be compared with those of the older European countries. After a motor car tour through Europe, the returning American becomes painfully aware of the fact that in this most important matter, his countries, even if we allow for its comparative youthfulness, in many decades behind that stage of development to which its wealth and enterprise should have carried it long ago. Although we say this with full appreciation of the fact that some of our States, and notably New Jersey and Massachusetts, have done effective work in building up a system of highways, the fact remains that, taken as a whole, the United States has not done much more in this matter of good roads than make a beginning. The work has yet to be done.

It is not that we have been parsimonious in the matter of appropriations. Had the money which has been voted by legislatures and county boards, and the enormous amount of work which has been done under the assessment method, been expended wisely in the first place, and followed up by intelligent methods of maintenance and repair—in other words, had we built our roads and cared for them as they build and maintain them in Europe, we do not hesitate to say that for the money and energy expended, our roads would have been in at least one hundred per cent better condition than they are today.

The fundamental requirements of a good road are an ample foundation and good drainage. Without these, the most carefully leveled and smoothly rolled top surface is nothing more than a delusion and a snare. Furthermore, a road which has been built with deep foundations, good drainage and an ample depth of suitable top dressing—unless it be watched and tended with the most solicitous attention—will go to pieces only a little less rapidly than the cheap product of the scraper and horse roller.

We have long believed that in those districts where scarcity of travel and financial inability to provide the necessary funds prohibit the construction of a first-class macadam road, it would be better to invest the time and money in constructing short sections of durable road, leaving the traffic to fight it out with "chuck holes," deep ruts and mud over the balance of the highway during the winter months. The endurance of a few years of discomfort would be repaid by the ultimate possession of a permanent first-class highway. Moreover, the use of oil or some other of the many excellent "binders" that are now available would make it possible to maintain the unimproved roadway in as good it not better condition than that of the old scraper-and-roller highway, which invariably went to pieces after the first two or three frosts and rains of the winter.

In districts where financial conditions and the amount of traffic has warranted the construction of expensive roads, millions of dollars have been thrown away because of the absolutely absurd system of maintenance (if it can be called such) which has been followed. There is no method of construction upon which eternal vigilance is so necessary as on that of the modern macadam highway. This has long been recognized in Europe, where the roadways are divided into comparatively short sections, each of which is controlled by a section gang, provided with a supply of broken rock, gravel, sand, or other road mending material, conveniently distributed in piles along the roadway. Each member of the gang has his wheelbarrow, pick and shovel, and as soon as the slightest indication of breakdown, such as a rut or hollow, is detected, repairs are made before the damage can proceed any further. A century of experience has proved that this is the only way in which a road can be maintained always in absolutely first-class condition, never was the truth of the old adage "A stitch in time saves nine" more strikingly true than in this matter of the upkeep of public thoroughfares.

Sound in the Universe

WE live and move at the bottom of an ocean of air, the earth's atmosphere. One consequence of this is that every mechanical disturbance starts waves of compression and rarefaction, which radiate out from the source, and, striking the drum of our ear, may (if of the right strength and quality) cause in us the sensation of "sound." Among such sensations some affect us merely as "noises", in others we recognize a more or less well-defined "musical pitch" and "tone quality." Physically the "noise" differs from the "musical note" in that the former is an irregular disturbance, while the latter is periodic and of definite frequency. Not that there is any hard and fast line of demarkation, a rapid succession of impulses, which separately would be mere noises, may impress the ear with a definite sense of pitch. Thus the teeth of a saw, cutting in rapid sequence through a wooden board, produce a sound of definite pitch, though lacking perhaps in musical quality. Or again, a sharp noise of brief duration, proceeding from a point in the neighborhood of a series of equidistant obstacles, such as a line of fence-rails, or a flight of stone-steps, produces upon the observer a sensation in which a more or less well-defined pitch can be recognized. The explanation of this phenomenon is that the sound is reflected back from each fence-rail in turn, and since it takes time to travel, each echo reaches the observer a trifle later than that from the neighboring rail. This case is of special interest, because the sound "heard" contains an element quite foreign to the initial disturbance. Furthermore, the pitch of the sound heard differs according to the location of the observer, so that, borrowing an expression from optics, it might be said that the original disturbance is "analyzed" by reflection from the fence (grating) into its "constituent" waves—each traveling in its own direction, so that it can be singled out by the observer. It is possible that the means commonly employed to analyze light waves act in this way, and perhaps we are not quite justified in imagining "white" light for instance as "composed" of the various spectral colors, these being rather impressed upon it by the prism or grating or other device employed to analyze" the light, as we commonly say.

Of all the forms of energy, sound would probably be of the least consequence to man, were it not for the one important fact, that sound is the normal vehicle for the transmission of intelligence between individuals. Certain special sounds are recognized by us not merely as "noises," or "musical notes," but as "words," which are associated in our minds with definite concepts, and whose mere mention immediately summons up before our imagination the concepts thus attached to them. Not that speech exhausts all the modes of sound-expression for mental states at our command. Indeed, more elemental and lower in the scale than speech are various inarticulate sounds, such as laughter and crying, calls of various kinds, the groan of pain the sigh of relief, the shriek of fear, and a host of other emotional expressions. In these man approaches more nearly to the lower animals, who also possess "calls." But the range of our modes of expression by means of sound extends also on the other, the heroic side, beyond ordinary speech. The poet by rhythm and cadence conveys something more than his words alone would say, and in the symphonies of the great masters of music there is borne in upon us a wealth of thoughts that lie too deep for words.

If the ocean of air which envelops us is the medium that carries sound to our ears, and thus places us in sentient communication with the other occupants of this globe, its shore, the void upon which the upper atmosphere abuts, is also the extreme limit of the range of space comprising all things audible to us. No sound, however loud, can ever pass from the earth into space beyond, neither can it penetrate from other orbs to us. The sun's burning eye looks down on us in splendor mute; for though his fiery ocean be lashed by furious gusts, in comparison with which the fiercest earthly gale is but as the soft sighing of the autumn wind, or as the breath of one that slumbers, and though monstrous explosions rend his very bowels, belching aloft great pillars of fire that tower thousands upon thousands of miles, yet of all the crash and thunder and tumult not a whisper escapes to break the eternal silence of infinite space, and the empty void holds close the clamorous secret of the fiery orb.

Seismology in America

THE United States has heretofore lagged behind most other civilized countries in the cultivation of the science of earthquakes, and to this day there is no chair of seismology or department of seismology in any American university.

Shortly after the San Francisco earthquake of April, 1906, a number of scientific men on the Pacific coast organized the Seismological Society of America, which now has a large membership well distributed over this continent, and beyond. We are glad to record the appearance, beginning with last March, of the quarterly *Bulletin of the Seismological Society of America*, published at Stanford University. In the initial number of this publication Prof. Andrew C. Lawson gives a timely review of the status of seismology in this country; while elsewhere in the *Bulletin* appears a list of all the seismographs known to be in operation in North and South America and the West Indies. Probably few scientific men realized how numerous these instruments have become on this side of the Atlantic. Forty-three are enumerated within the United States. The Jesuit colleges are especially notable for the zeal with which they have extended and organized such installations.

Prof. Lawson appeals to the Carnegie Institution to undertake the direction of seismological work in America. At present such work lacks organization, and the seismological stations are badly distributed, they are crowded in some sections and very sparsely distributed in others. The attitude of the government toward seismology is strangely at variance with its general policy in regard to other branches of science. It was proposed a few years ago to equip a number of stations of the Weather Bureau with seismographs, and this proposal was urged upon Congress by a committee of the American Association for the Advancement of Science. As the Bureau has some two hundred regular meteorological stations scattered over the country, manned by paid employees, the additional expense entailed in adding seismological work to its duties would not be considerable, and such an addition would be in accord with the policy of most foreign countries, where seismological observations are generally made under the direction of the official weather services. In spite, however, of the urgent recommendations of the Chief of the Weather Bureau in behalf of this proposal, it was rejected by Congress, and the Bureau possesses, up to date, only the seismograph installed at its central office in Washington.

Another appeal was made to Congress last year to establish a bureau of seismology under the Smithsonian Institution. Although the bill introduced to this effect carried with it an appropriation of only $20,000, it never passed the committee stage in Congress.

It might be supposed that the State of California, after its painful experience of 1906, would be liberally disposed toward the science that has for its practical aim the amelioration of the effects of earthquakes, but such is not the case. It is practically impossible to secure State aid to seismological investigations in California because the commercial spirit of the people fears that such investigations would advertise California as an earthquake region and hurt business.

We are not in a position to say what attitude the Carnegie Institution will take toward Prof. Lawson's proposal that it take over the national control of seismology. Such action would, however, be a departure from the settled policy of the Institution, which is opposed to the assumption of duties that properly belong to the national government. That the study of earthquakes falls within this category cannot be doubted.

The Guardian of Ninety Million Stomachs

Dr. Harvey W. Wiley of the Bureau of Chemistry

By William Atherton Du Puy

BECAUSE one man saw a great light, because he was a great scientist, a great politician, a great philosopher, a great fighter, a great publicity agent, the ninety million have come to have dependable food on their tables three times a day. Because this man lived and fought, the babies of a nation are no longer drugged into degeneracy and death. Because of his activities the adults of a nation are no longer unknowingly acquiring drug habits that sap their vitality. Because of the standard his influence has set in the matter of pure foods and drugs a new spirit is abroad in the land which promises to put all lines of business on a basis of honesty that they have never known before.

For Dr. Harvey W. Wiley, chief chemist of the Department of Agriculture, has so wrought as to bring to bear upon the every day lives of all the people an influence among the greatest of any man of his time. He has a theory that the man of to-morrow is a product of what goes into his stomach to-day. He set out long ago to make better men through giving them better food and preventing the injuries that were being done them through deceptive drugs. He has encountered stupendous difficulties.

And now, suddenly, his enemies execute a coup that was intended to prove his undoing. He is charged with irregularity in the employment of a necessary expert at a salary of $1,600 a year. It is recommended that because of this alleged irregularity all the accomplishments of his thirty years of labor be set aside and that he be summarily dismissed.

But the ninety million have insisted on being heard from. They have arisen *en masse* and have used every organ at their disposal in voicing their displeasure at the proposal to remove the pure food expert. There never was a salary of $1,600 paid to an expert, legitimate or otherwise, that so aroused a nation or promised so many embarrassments to men high in public life.

All this calls particular attention to Dr. Wiley, whose activities have been a matter of comment for a quarter of a century, whose personality has given him a position that is unique, yet whose enemies, though few, are powerful, for the money of all the illicit business he has disturbed is back of them.

Dr. Wiley is an interesting character. His father was an Indiana farmer of Scotch descent who mastered Greek unaided and preached thirty years without pay. His son grew up on a farm and became the champion corn planter of the neighborhood. He paid his way through Hanover College with money he earned doing manual labor on the farm. Later he taught and saved money for a year at Harvard, then taught at Purdue. He became State Chemist in Indiana and in 1882 investigated maple sugar adulterations, one of the first food investigations the United States knew. The following year he was made chief chemist of the Department of Agriculture, a position so obscure that its only duty was passing upon the mixture of fertilizers. This was twenty-eight years ago and with the growth of the Bureau of Chemistry from fertilizer mixing to the supervision of the foods and drugs of a nation has been the growth of Wiley, for he has been the Bureau of Chemistry.

Dr. Wiley is now a man of sixty-eight years of age, a great, hulking man, six feet tall, weighing 220 pounds, in perfect health and apparently twenty years younger than he is.

Soon after Dr. Wiley became associated with the Department of Agriculture he began his pure food investigations. In Indiana had been born an ambition which was nothing less than giving the people of the nation honest food. Everywhere there was deception in the things that were sold. If one bought pepper it was eighty per cent ground up shells. If one bought meat it was "embalmed." If one bought fruit it was pickled in injurious chemicals. If one bought proprietary medicine it might have any amount of opiates in it without his knowledge. There was no dependence to be placed in labels and names. Wherever money was to be made through deception, deception was being practiced. The whole people bought, as food, substances with little nourishment in them. More than that, they were being deceived into putting things into their stomachs that were cryingly injurious to them.

The people did not know this. They were busy with other things and little interested in being told. Even when convinced they did not know what to do about it. They had to be informed, interested, and led to act. It is no mean task to lead the public through these stages. But Dr. Wiley was the man with the particular qualities to accomplish these things. In the first place he was thoroughly aroused over the food question. In the second place he was willing to work night and day, year after year, on this one job. In the third place he had the happiest faculty of the publicity man that has ever been bestowed to an individual.

DR. HARVEY W. WILEY

The chief of the Bureau of Chemistry of the Department of Agriculture.

Dr. Wiley's greatest asset in his campaign for pure foods has been his ability to get into the papers. He is the most sociable man on earth. He is an artist as an after-dinner speaker. He is a clubman. He accepts many invitations, especially where there is a chance to make an after dinner speech. Then he talks for the newspapers chiefly about pure food. He has the gift of talking in headlines. There is an epigrammatic sensation in every one of his speeches. He always makes a "story" that gets on the front page, a "story" that calls public attention to some food abuse. The same is true when he talks to reporters. There is not a newspaper man in Washington who does not fall back on Dr. Wiley whenever he has failed to get something to write elsewhere. It was through publicity that he finally got his message to the masses. They came to know the dangers that beset them through the food they ate, and they came to understand the possibilities of removing these dangers. The campaign of publicity finally ended in the passage of the Pure Food and Drug Act of 1906, which was put in operation under the guidance of the chief of the Bureau of Chemistry on January 1st, 1907.

But with the passage of the law the troubles of the chief chemist were but just begun. Previously his campaign had merely been educational. Now it was administrative. The blacklisting of a given drug or a given food meant the antagonizing of the interests back of that food or drug. Millions had been made in the manufacture of patent medicines that made their reputations for cures by the soothing effects of the opiates they contained. Those millions were to be destroyed by the prohibitions of Wiley. Other millions were being made in an adulteration of various foodstuffs and by their preservation with injurious chemicals. The public was being tricked by the use of dyes and coloring matters. Fortunes were made by branding an inferior article as something better. In the aggregate it is estimated that $400,000,000 in invested capital was arrayed against this one man. That capital was determined to destroy him. His position was political. Big money is prominent in politics. It has long played politics in an attempt to get rid of Wiley.

A trial involving the use of a food preservative was recently held in Indianapolis. Dr. Wiley was refused permission to go to Indianapolis to testify. The court sent a committee to Washington to get his affidavit.

"Do you realize," Dr. Wiley was asked, "that the defendants in this case represent an investment of $10,000,000?"

"Probably so," responded the chief chemist, "but if there was at stake the life of but one baby instead of thousands, I would place that life above the interest of the capital invested."

The Wonderful Mechanism of the Watch

FEW pieces of machinery show more marvelous features than that of the watch. As a general proposition it may be stated that a watch is the smallest, most delicate instrument of the same number of parts that has ever been devised. About one hundred and seventy-five different pieces of material enter into its construction, and upward of twenty-four hundred separate operations are comprised in its manufacture.

Certain of the facts connected with its performance are almost incredible when considered as a whole. A blacksmith strikes several hundred blows on his anvil in a day and, as a matter of course, is glad when Sunday comes, but the roller jewel of a watch makes every day—and day after day—432,000 impacts against the fork, or 157,680,000 blows during the course of a year, without stop or rest—or some 3,153,600,000 blows during the space of twenty years, the period for which a watch is usually guaranteed to keep good time.

But the wonder of it does not cease here. It has been calculated that the power that moves the watch is equivalent to only four times the force used in a flea's jump. The watch power is, therefore, what might be termed the equivalent of a four flea power. One horse power would suffice to operate 270,000,000 watches.

Furthermore, the balance wheel of a watch is moved by this four flea-power one and forty-three one hundredths inches with each vibration, or 3,558¾ miles continuously in one year.

Not much oil is required to lubricate the little machine on its 3,500 mile run. It takes only one-tenth of a drop of oil to oil the entire machinery of a year's service.

Lung Capacity as Affected by Corset-wearing

THE lung capacity of the average woman who does not wear corsets is about 2800 cubic centimeters or 171 cubic inches, of one who is in the habit of wearing corsets only 2,200 cubic centimeters or 134 cubic inches, so that the capacity of the normal and unrestricted lungs is about 27.3 per cent more than that of those which have been compressed by the corset.

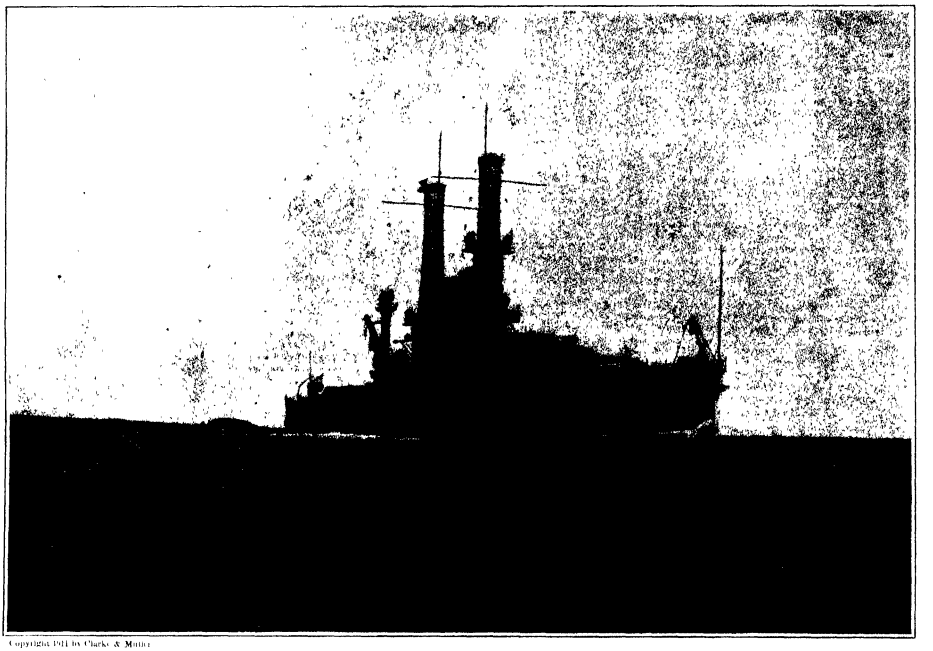
The Battleship "Utah"

Our Latest Dreadnought

THE work of upbuilding our modern navy goes on apace. Although the progress is not as rapid as some of us could wish, in quality we are more than holding our own, for what we lack in numbers we gain in gun power and in the high quality of the personnel.

We present an illustration of the latest of our dreadnoughts, the "Utah," which, with her sister ship, the "Florida," now approaching completion at the New York Navy Yard, represents an advance in many important particulars, on the "Delaware" and "North Dakota." The illustration is from a photograph taken during the recent speed trials of the "Utah" over the Government course at Rockland, when she considerably exceeded her contract speed of 20.75 knots, the maximum average speed being 21.8 knots.

The "Utah" was authorized by Congress on May 13th, 1908. The contract for her construction was let to the New York Shipbuilding Company at Camden, N. J. on November 24th, 1908. Her keel was laid March 15th, 1909. She was launched December 23rd of the same year, and the contract date for her completion was July 24th, 1911. She will probably be delivered over to the Government early in August.



It will be noticed that in her general appearance she conforms closely to the "Delaware" and "North Dakota," having two cage masts, two funnels, and mounting ten 12-inch guns in five turrets placed on the longitudinal center line. Two of the turrets are placed forward of the conning tower the guns of the after turret firing above the forward turret, the ship being thus able to fire four 12-inch guns dead ahead and through a wide arc of training on either beam. The three remaining turrets are placed aft of the mainmast, the foremost of these three being carried to an elevation sufficiently higher than the after two turrets to enable its pair of guns to fire above their roofs, thus giving a concentration dead astern and through a wide arc of training on each beam of four 12-inch guns. Because of the center line position of all the turrets, the whole battery can be trained through an unusually wide arc on either beam of the vessel.

The "Utah" is 521½ feet in length over all, or about 3 feet longer than the "Delaware," and she exceeds that ship in beam by 3 feet, the "Delaware" being 85 feet 2½ inches broad, and the "Utah" 88 feet 2½ inches. She also draws about a foot and a half more water at her mean draft, which is 28 feet 6 inches. As the result of this enlargement, her displacement at normal draft, when she is carrying two-thirds of the full supply of stores and fuel, and a full supply of ammunition, is 21,825 tons, as compared with 20,000 tons displacement of the "Delaware" when she is carrying two-thirds of her full supply of ammunition and stores. When fully loaded her displacement is 23,033 tons.

The "Utah" is driven by Parsons turbines whose power is delivered to four propellers. The contract called for a speed of 20.75 knots, with 28,000 horsepower, but on trial, as we have seen, she exceeded this by fully one knot. Her bunker capacity is 2,500 tons of coal, exclusive of 400 tons of oil fuel.

The defensive elements of the "Utah" are unusually complete. The main belt is 7 feet 11½ inches wide, extends 6 feet 6 inches below the water line, has a thickness at the top of 11 inches, and at the bottom of 9 inches. The upper belt, which extends to the gun deck, has a thickness of 10 inches at the bottom, and 8 inches at the top. The casemate armor is 6½ inches in thickness, and it is associated with 1½-inch splinter bulkheads. The barbettes are protected by 11 inches, and the turrets by 12-inch front and 8-inch side armor.

The battery consists of ten 50-caliber, 12-inch guns, and sixteen 5-inch, 50-caliber guns for protection against torpedo boat destroyers and torpedo boats. There are two submerged torpedo tubes, for the discharge of the new high-speed 21-inch torpedo, which has an effective range of over 4,000 yards. An important feature in these ships is the good command of the guns, due to the sufficient freeboard of the ship. Forward, the freeboard of the "Utah" is about 26 feet, and aft about 18 feet. The guns of the foremost turrets are about 31 feet above the water, turret No. 2 about 28 feet, turret No. 3 about 29 feet, and turrets Nos. 4 and 5 about 28 feet above the water. When the "Utah" goes into commission she will be in command of Capt. W. S. Benson.

Copyright, 1911, by Clarke & Moore.

Displacement, with two-thirds stores and fuel and full ammunition supplies, is 21,825 tons. **Speed,** 21.8 knots. **Coal,** 2,500 tons. **Oil,** 400 tons. **Armor:** Main belt, 11 to 9 inches; upper belt, 10 to 8 inches; barbettes, 11 inches; turrets 12 to 8 inches. **Guns:** Ten 50-caliber 12-inch; sixteen 50-caliber 5-inch. **Torpedo tubes,** two 21 inch. **Complement,** 984.

OUR LATEST BATTLESHIP—THE "UTAH" STEAMING 21.8 MILES ON HER SPEED TRIALS

Pigments from Odd Sources

THE ingenuity of the manufacturers of pigments for the use of artists has been so severely taxed within recent years that they have been obliged to employ for the purpose all manner of animal, vegetable and mineral substances. Even Egyptian mummies have been utilized in this way by the manufacturers.

It appears that the corpse of the old Egyptian was preserved in the finest bitumen, and that the remains thus treated in the centuries gone present, on being unwrapped to-day, an appearance quite like that of light-colored leather. Now it has been discovered that, when the bitumen and the leather-like remains are ground down by machinery, there is obtained therefrom a beautiful brown pigment, especially prized by painters of portraits, who claim that this pigment is particularly effective in depicting certain shades of brown hair.

Among the other colors obtained from strange sources may be mentioned Prussian blue. This is made by fusing the hoofs of horses with impure potassium carbonate.

Sepia is the dark fluid discharged by the cuttlefish to render the water opaque for its own concealment when attacked by its enemies.

The cochineal insect furnishes crimson and purple lake and carmine, while ultramarine is procured from the precious metal known as lapis lazuli.

Raw sienna is natural earth from Sienna, and, when burnt, becomes burnt Sienna. Gamboge is the yellow sap of a tree that grows in Siam.

A Sun-dial as an Accurate Time-piece

A Spot of Light That Tells the Time of Day

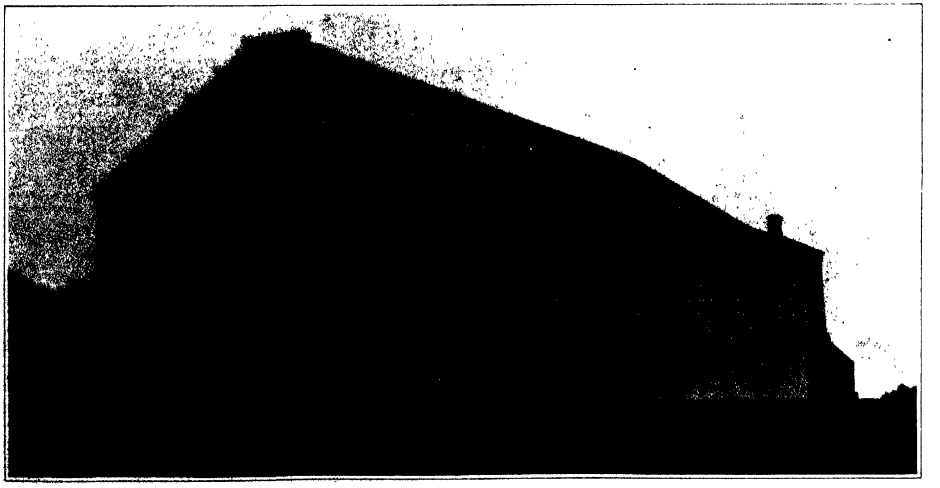
IN these days of accurate clocks and watches no one thinks of using a sun dial to tell the time of day. At best such an instrument can be right but four times a year, and in many places it can never agree with standard time. Yet the demand for sun dials was probably never greater than it is now, merely because, as an ornament, it adds a quaint and picturesque touch to the lawn or garden, or else it harmonizes well with the architectural treatment of a building. As standard time is obtained primarily from the sun, with due allowances for its variations from noon to noon, there is no reason why a sun dial should not give us accurate time if we make similar allowances.

A novel sun dial in which such regulation can be made is illustrated on this page. This dial differs radically from the common type. Instead of showing the time of day by a shadow cast by the sun, it employs a spot of direct sunlight which is brought to bear upon a hair line on a white screen. The dial of the instrument is tilted according to the latitude, so that it will lie parallel to the plane of the celestial equator. The photograph shows the instrument set for the latitude of New York. The base must be oriented accurately, and the dial face tipped to the latitude of New York (which is about 41 degrees), the upper angle being found by means of the graduated sector on which the dial face is supported. The dial proper is divided into equal divisions to indicate the hours of the day, and opposite the 6 A. M. and P. M. marks are two upright brackets, one of which serves as a screen (at the left in the illustration), while the other contains the perforations through which the sun shines, making a spot of light that falls on the screen. As the face of the dial is parallel with the celestial equator, its edge forms an artificial horizon, along which the sun apparently travels. Because the sun mounts above the celestial equator in summer time, and falls below it in winter, two holes are formed in the bracket at the right, one above the other, so that the spot of light will be sure to strike the screen through one or the other of these holes at any time of the year. In order to allow for variations of the sun, the bracket containing the two apertures is made adjustable in the following manner. On the face of the dial will be noticed a smaller dial marked with the months of the year, while adjacent to it is a scale divided into thirty-one equal parts representing the days of the month. If the reading is to be taken on, say, February 6th (as shown in the photograph), this small months' dial must be moved to bring the February mark in line with the sixth mark on the scale. An elliptical cam is connected to the months dial, and engages an arm to which the bracket is connected, thereby shifting the bracket laterally, according to the position of the dial. In February, the sun time is nearly a quarter of an hour slow, consequently the bracket is moved upward or eastward a corresponding amount. This done, the main dial is turned until the spot of light passing through the lower aperture is bisected by the hair line of the screen. The reading of the time is then taken upon a small scale shown at the right in the engraving. This is divided to indicate minutes, and in our illustration the time is shown to be 4.20. When the instrument is first set up the minutes scale must be adjusted so as to harmonize mean local time with standard time. As the sun passes over New York (on the 74th meridian) four minutes before it reaches the 75th meridian, on which New York standard time is based, the minutes scale must be set to read four minutes slow in order that the time as shown by the dial will agree with standard time.

SUN-DIAL THAT GIVES CORRECT STANDARD TIME

We who live in regions where there are plenty of clocks and timepieces of precision hardly realize the practical value of such a dial. In sparsely settled localities, for instance, on remote plantations, an instrument that will give correct time to the minute, obtaining this time directly from the sun, should be almost indispensable.

Casting Cement Building Walls on the Ground



A Church Built in a Novel Way

THE accompanying illustrations show a method of a new system of reinforced concrete building construction, in which the church walls are erected by means of raising jacks.

On the foundation wall and on piles inside of the building lot are set a series of jacks made of steel. These jacks consist of a supporting carriage, a pivoted walking beam, and a collapsible screw driven by a worm gear and worm. A platform is laid on the jacks and on this platform are set in their proper relative positions, all door-frames, window frames and other openings. The concrete is poured around the opening thus established. The reinforcement is easily and properly placed horizontally and vertically, because the wall resembles a great draughting board and is very readily "laid out." The entire wall is poured at once, which can be done in a single day, even though the wall be 200 feet long and three stories high. After the wall is finished it is allowed to set for forty-eight hours, then a small gasoline engine or electric motor is connected with the driving shaft, and the wall rises from the inside slowly and quietly to its permanent vertical position.

When all the walls are in place the corners where reinforcements from either wall project and interlock are poured and we have a complete monolithic, well finished structure. Floors and roof of concrete or of any construction desired are put in place in the same way as in any other building.

No forms are used whatsoever in this wall construc-

THIS STRUCTURE WAS BUILT IN SECTIONS FLAT ON THE GROUND

tion except the wooden jack platform, which is never destroyed, but is used over and over again An air space can be made merely by filling in with loose sand which is rodded out when the concrete sets and the wall is partially raised The reinforcement is placed both horizontally and vertically exactly where it belongs in both inner and outer wall It is possible to use rods, fabric or any other kind of reinforcement without the slightest difficulty

An Airman's Weather Bureau

DO YOU remember how, in Kipling's "With the Night Mail," the Mark Boat flashes news of the wind and weather along the several "levels" so that the aerial liners may take advantage of favorable currents, and avoid the besetting dangers of the sky so graphically described in the same prophetic tale? It was only yesterday that Kipling dreamed his dream—of "the year 2000"—and to-day we stand upon the threshold of its realization

Not to dogmatize about the future and assert that the airman will always be more at the mercy of the elements than the seaman, and that consequently the cultivation of aerial meteorology will be more urgently imposed upon our posterity than that of maritime meteorology is upon our contemporaries, we are safe at least in declaring that in the year 1911 such is decidedly the case The sea has been robbed of nearly all its terrors Even *mal de mer* is an anachronism and a solecism on a "Mauretania" or "Olympic" The dangers of the air are not yet even half appreciated

To the meteorologist, already burdened with the heavy responsibilities imposed upon him by the mariner and the farmer, the producer and the transporter of perishable goods, the seeker of health and the seeker of pleasure, has suddenly been assigned the twofold task of charting the aerial ocean and giving the aeronaut timely warning of its dangers

That meteorology is even now ready to enter upon its new duties is the confident belief of Dr Richard Assmann, director of the Royal Prussian Aeronautical Observatory of Lindenberg

The noble institution over which Dr Assmann presides—situated some forty miles southeast of Berlin—was fully described in the SCIENTIFIC AMERICAN SUPPLEMENT of July 13th, 1907 It has been, ever since it was founded, the heart and brains of "aerology" in Germany, its contributions to meteorology have been almost epochal, but its enormous practical significance to aeronautics has only recently begun to be realized

In a long article on "The Dangers of Aerial Navigation and the Means of Diminishing Them," contributed to the *Deutsche Zeitschrift fur Luftschiffahrt*, Dr Assmann a few months ago described, among other things, the aeronautical weather service that he was then organizing, and which with Lindenberg Observatory as its center, is now in full operation Dr Assmann's account of his new undertaking is summarized in the following paragraphs

It should be stated at the outset that at least three tentative schemes of this sort had previously been put into execution in Germany, though on a relatively small scale The first was undertaken by Lindenberg Observatory in 1907 on the occasion of the trial trips of the "Parseval," observations of the upper air-currents were made simultaneously at five stations by means of pilot-balloons and communicated to the crew of the airship, who were thus materially aided in shaping their course The second similar undertaking was Dr Linke's special weather service for aeronauts in connection with the aeronautical exposition at Frankfort—the "Ila" (I L A, Internationale Luftschiffahrts Ausstellung)—a notice of which appeared in the SCIENTIFIC AMERICAN of June 18th, 1910, pp 511-512 The third aeronautical weather service was organized by Dr Polis, at Aachen, and is still in operation. It is intended especially for the benefit of the many aero clubs of the Rhineland, but its utility was conspicuously demonstrated during last year's army maneuvers in West Prussia

These local and quasi-experimental undertakings have paved the way for a national aeronautical weather bureau For the moment its field of operation is northern and central Germany—i e, Prussia and the states that are especially under Prussian influence—but its extension to the remaining German States will follow as soon as the wheels of diplomatic machinery have performed the requisite number of revolutions Political heterogeneity still hampers imperial undertakings in Germany to a degree that Americans find it difficult to realize

If we examine the facilities available for the proposed extension of the domain of practical meteorology to the upper air, we find that Germany is much better prepared for such an undertaking than the other European states Four years ago the Prussian Government decided to infuse new life into its weather service, especially with a view to the requirements of agriculture. The Ministry of Agriculture, Domains and Forests established in Prussia and the neighboring states, independently of the previously existing meteorological institutes, a network of seventeen forecasting and map-publishing weather stations, modeled, in a large measure, after those of the United States Weather Bureau Dr. Börnstein, of Berlin was a leading spirit in this undertaking, and Dr. Polis, of Aachen, spent two months in the United States, inspecting the methods and *matériel* of the American weather stations Germany's new Public Weather Service is now in vigorous operation, and represents an intensive application of the methods of applied meteorology that is hardly paralleled elsewhere outside of the United States

In the summer of 1909 the writer of this summary paid a visit to Dr Hergesell, president of the International Commission for Scientific Aeronautics, at Strasburg This distinguished aerologist was even then urging the equipment of the Public Weather Service stations with pilot-balloons, in order that daily observations of upper-air currents might be secured at many points throughout the empire for the information of forecasters. It is, however, significant of the mode in which scientific ideas unfold themselves, step by step, that in the course of a half-hour's conversation on this subject Dr Hergesell never once suggested the advantages that the adoption of his project would offer to aeronauts—notwithstanding the fact that he is an aeronaut himself and had at that time made several voyages with Zeppelin So far as the writer can recall, his point of view was entirely meteorological, the forecasts that he hoped to improve were those applying to land and sea, and certainly the same may be said of his writing at that period, as well as those of Querpain, Schreiber, Kremser and the other enthusiastic advocates of the pilot balloon.

The hopes of Hergesell are now being realized, but the point of view has shifted Lindenberg Observatory has now equipped the Public Weather Service stations with the apparatus needed for daily observations of the upper air, not primarily for the purpose of improving the regular weather forecasts, but in order to secure the means of lessening the dangers of aerial navigation—dangers, in Assmann's opinion, largely avoidable, which cost twenty valuable lives in Germany during the year 1910 alone To-day the aeronaut launches his craft with no more knowledge of the meteorological conditions in the upper air than can be vaguely surmised from those depicted in the ground-surface weather map. To morrow he will have a weather map all his own, representing, as a rule, quite a different set of conditions from those prevailing at the lower level

The details of the plan by which this desideratum is being accomplished can best be stated in its originator's own words We quote from his memoir, referred to above, which was written a few weeks before the new service began its work.

"A number of the Public Weather Service stations, or better, if the cost does not prove too great, all of these stations in northern and central Germany, are to be furnished by the Lindenberg Observatory with a theodolite, an inflating-balance for determining the ascensional force of the balloons, a sufficient number of rubber balloons, and the necessary graphic tables for rapidly working up the observations Where it is not practicable to provide compressed hydrogen gas in steel tanks, a Naas-Gradenwitz gas-generator will be supplied

"The stations will be expected to send up a pilot-balloon at 8 A M on every day when the weather and state of the sky are favorable, and to follow its course with the theodolite as long as possible. The observation will then be worked up—a matter of barely a quarter of an hour for a practised observer—and telegraphed in cipher to Lindenberg Here the observations received from all the stations will be assembled, and redistributed, in a single telegram, to each of the co-operating stations, where, if they arrive in time, they can be utilized in connection with the ordinary daily weather forecast, as well as in preparing special forecasts and warnings for aeronauts At Lindenberg the regular observation with a kite or captive balloon is made daily at 8 A. M., and in summer an observation is also made about 5 or 6 A M These furnish not only data concerning the wind such as are obtainable with a pilot-balloon, but also data of the other meteorological elements It is also proposed to make a daily observation at Lindenberg with a pilot-balloon at 11 A. M., and whenever circumstances require another about 2 P M., so that soundings of the air up to an altitude of several thousand meters will be made three or four times daily within a period of from six to nine hours, affording valuable information as to rapid changes in the upper atmosphere. It is hoped that it may be found practicable also to make a midday observation at some of the other stations, especially at the kite-station of the Deutsche Seewarte, at Hamburg, which is already well equipped for such work.

"It is altogether likely that the Public Weather Service stations will be supplemented with stations especially erected for the purpose at the larger aviation fields, airship sheds, and the like. One of these has already been assured at Bitterfeld. Another important addition to the aerological *réseau* will be the 'Aeronautical Observatory on the Inselberg,' near Gotha, the erection of which has been intrusted to the authorities of Lindenberg Observatory by the Duke of Saxe-Coburg-Gotha, and which will be installed next spring. There is also a prospect that the long-promised aerological station on the Taunus will soon be erected, and will contribute its part to the new service. Lastly, aerological stations will probably be installed at certain nautical schools on the coast, thus providing observations from a region that is particularly dangerous to the aeronaut

"While pilot-balloons afford the easiest and cheapest method of exploring the upper air, they labor under the serious disadvantage that they cannot be used in foggy weather, or even when the clouds hang very low. During the winter months, especially, one cannot count upon obtaining observations by this method up to one or two thousand meters more than about half the time. This of course applies especially to an early morning observation, at a fixed hour, toward midday there is a better prospect of clear sky, especially if one is on the alert to take advantage of occasional breaks in the clouds. As a measure of economy, the stations will be supplied with balloons of two sizes; the smaller and cheaper to be used when it is evident that the state of the sky will not permit the balloon to be followed with the theodolite to a great distance. In special cases it may be possible to make observations at night by the use of the illuminated balloons manufactured by Saul of Aachen, this method, however, is relatively expensive.

"There will, however, undoubtedly be many days on which few if any observations can be secured with pilot-balloons, and observations will be available only from stations equipped with captive balloons and kites In order to meet this serious difficulty, the Lindenberg Observatory is considering the plan of supplying a few selected stations with a simple and easily manageable kite-outfit."

This plan leaves to be considered only the relatively infrequent case of cloudy or foggy weather combined with a calm air, in which a kite could not be raised The obvious way out of this difficulty, if the expense did not forbid, would be to further equip the stations with captive balloons, carrying self-registering apparatus However, Dr. Assmann admits that such an expedient must be relegated to "a happier future"

The plan outlined above was approved by the German Government and, in its main features, went into operation January 2nd, 1911 Funds have subsequently been granted that insure the continuation of the enterprise at least until April, 1912 The service is being used to the fullest extent by the many aeronautical societies of Germany, and is adapting itself to practical requirements in various ways not contemplated in the original programme Thus it is interesting to notice that special arrangements were made for supplying meteorological information to the participants in the great "Rundflug" of June 11th to July 7th; two officials of the service were detailed to accompany the fliers, and to make frequent observations of the upper air-currents, with pilot-balloons, at the beginning of each stage of the course, and all stations were expected to make and telegraph aerological observations three times a day during the period in question

It is hoped that the field of observation will soon include the South German States; especially as this would bring to the enterprise the valuable co-operation of the so-called "kite-station" at Friedrichshafen, on Lake Constance, which is really a "balloon-station," as the wind over the lake is rarely strong enough to raise a kite, even though aided by the motion of the small steamboat from which the apparatus is flown, and much the larger part of the daily observations are made with captive balloons. One of Dr. Assmann's cherished plans is the erection of a similar "floating kite-station" on Danzig Bay, as an appendage to the Lindenberg Observatory.

The founder of the aeronautical weather service realizes that his plan is open to the objection applying to weather services generally; viz., it cannot hope to provide detailed information and forecasts of local conditions except in so far as these may be inferred from the general outlook. To revert to Kipling, one of the gravest situations in which the aeronaut may be placed arises "when the Heavens are balancing their valt-accounts;" and to forecast the occurrence and movement of a thunderstorm from the observations of a few widely separated stations is a well-nigh hopeless undertaking. Is it feasible to secure a corps of

special thunderstorm observers reporting by telegraph and telephone large enough to enable the forecaster to follow the progress of these disturbances across the country and give timely warning to the aeronaut to get out of their path—possibly using wireless telegraphy for transmitting the warnings? Dr. Assmann thinks so and has even made a detailed estimate of the probable expense. However, this is not part of the programme definitely formulated for Germany's "airman's weather bureau."

SPECIAL WEATHER SERVICES FOR AERONAUTS.

In Germany it has become the regular practice to organize a special meteorological service in connection with every important aeronautical competition. Some of these special services, as well as the permanent general service recently organized by Assmann, have already been described in the SCIENTIFIC AMERICAN. The most important undertaking prior to Assmann's was that of Dr Franz Linke in connection with the Frankfurt aeronautical exposition of 1909.

The *Deutsche Zeitschrift fur Luftschiffahrt* describes the weather service recently operated in connection with the German reliability flight in the upper Rhine district. A meteorologist traveled over the route with the contestants, making observations and issuing forecasts at each stopping-place. Three principal lines of work were carried out, viz. (1) The telegraphic weather reports of the Deutsche Seewarte were received and twice-daily forecasts were issued of the weather along the route (2) Each day, before the flying was resumed, the movement of the upper air was observed locally by means of pilot-balloons, the general behavior of the upper currents over Germany was determined from telegraphic reports of similar observations made at the fifteen regular pilot-balloon stations operating under the Lindenberg observatory, and the wind at the surface was measured with a portable anemometer (3) A special thunderstorm service was in operation Sixty observers, distributed over southwestern Germany, sent in an "urgent" telegraphic report whenever thunderstorms approached their respective localities This service proved to be especially efficient and useful; several thunderstorms occurred and the aeronauts were warned, at least an hour in advance, of the arrival of each of them

Freezing Experiments on Fish and Other Animals

SOME remarkable experiments were made not long since at the University of Geneva by M Raoul Pictet, whose name is intimately connected with the production of artificial cold He was, in fact, one of the pioneers in this field, which has now taken so wide a development In the course of some recent work he was able to take live fish, such as goldfish and many of the fresh water varieties with which we are familiar, and place them in a tank Then he freezes the water in which the fish are swimming, so as to form a block of ice Then he freezes the ice block still further, down to a low temperature, about 20 deg C. below freezing point, and keeps the whole at this point by means of a freezing apparatus for two or three months After this time the block of ice is thawed out very slowly, and the seemingly dead fish come to life and swim about as usual

This is the simple but most remarkable experiment which M. Pictet realizes, adding a new discovery to the important ones he has already made However, these latter relate mainly to industrial processes, while the present experiment is one of far-reaching interest to science in general. In a recent interview with the *Matin*, of Paris, M Pictet states that his first experiments upon life at very intense cold date nearly eighteen years back He became convinced that if the chemical reactions of a living organism could be suspended without causing any organic lesion, the phenomena of life would disappear, but these would come back as soon as the organism was restored to the usual conditions. Great cold will suspend the operations of life as far as we are able to observe, but without losing it totally. He made some very conclusive experiments upon fish, as we already noted, and these could be completely frozen and then thawed out without causing loss of life On one occasion, while working on this subject at the university, he put twenty-eight fish in a deep glass basin, and left them for twenty-four hours in water at about the freezing point. Then he froze the water to a solid block, together with the fish, going down to 20 degrees By breaking off part of the block, one of the fish could be taken out, and he found that it could be broken in small pieces just as if it were made of ice itself After thawing out the block, it is found that no harm has been done the fish, and they swim about just as if nothing had happened.

The freezing must not be carried down too far in the case of fresh water fish, and the temperature indicated above is about the lowest which can be used, otherwise the fish will be killed However, there are other animals which can stand a much greater amount of cold. Frogs come next in order to fish in this respect, and can be frozen down to 28 deg C below the freezing point Some water lizards or salamanders will stand more cold, or 50 degrees. He finds that snails will resist the greatest amount of cold among the specimens which he tried, and they can be frozen as low as 120 deg C below the freezing point, and will then come back to animation

Correspondence

The Invention of Artificial Rain Apparatus

To the Editor of the SCIENTIFIC AMERICAN

In your issue of April 15th, 1911, there appears an article on the production of artificial rain for agricultural purposes, in which article certain rain producing apparatus is described, the invention of which is credited to a German whose name is given as Hartmann

Permit me to call attention to the fact that the system of rain producing described in your article, which I notice is credited to the German periodical *Prometheus*, is my invention, and that I have secured the following patents on it

	Patents No
British	9,004
Australia	15,376
United States	958,937, 963,932
France	403,701
Belgium	211,923
Argentine Republic, 5,684, 6,392, 6,642, 7,170, 7,171, 7,944, 7,949,	8,292
Brazil	5,651
Chile	2,215
Uruguay	412, 474

Including four German claims now pending in the Imperial Patent Office in Berlin

I write this letter in order that any wrong impression that may have been created by the article from *Prometheus* may be removed

New York city EMILIO OLSSON

The Difference Between Light and Heavy Winds

To the Editor o the SCIENTIFIC AMERICAN

In the issue of May 20th, page 507, of the SCIENTIFIC AMERICAN, under heading, "Home-made Anemometer," the formula to obtain true velocity of wind is

$$P = 0.400 - S\,V^2. \quad \frac{B}{30}$$

Shouldn't this read $P = 0.004 - S\,V^2$? $\frac{B}{30}$

Would you please inform me just where you draw the line between light winds and heavy winds?

Pittsfield, Mass P. N. MOORE.

[Our correspondent has very properly called attention to an unfortunate typographical error in the article referred to The factor 0.400 was a misprint for 0.004

We may add that the factor $\frac{B}{30}$ (correction for barometric pressure) can safely be neglected when the place of observation is near sea level

The choice between the larger and the smaller windplates must be decided by the observer's experience in the use of the instrument. It will depend, of course, upon the strength of the spring and the length of the scale, as well as upon the force of the wind.

The whole subject of normal pressure-plate anemometers, and the various forms of such apparatus (the earliest of which dates back to the year 1724) will be found fully discussed in C. Abbe's "Treatise on Meteorological Apparatus and Methods," which was published as an appendix to the Annual Report of the Chief Signal Officer for 1887

It is hardly necessary to state that the rough-and-ready instrument described by Mr. Gilbert should, whenever possible, be compared with a standard anemometer—or, more conveniently, a Richard anemocinemograph, which shows the velocity of the wind directly, at a given moment—and its error thus determined.

Having obtained a fairly accurate instrument, it should be further borne in mind that the velocity of the wind near the earth's surface is nearly always very much less than that prevailing at the altitude of an ordinary aeroplane flight; and that the existing statistics of the variation of winds with altitude are mere averages, subject to wide fluctuation. On the whole, the anemometer is, as yet, of but moderate utility in aeronautics.—ED.]

Self-luminous Night Haze

UNDER the above title Prof E E Barnard, of the Yerkes Observatory, publishes in the *Proceedings of the American Philosophical Society* an important contribution to the subject of nocturnal sky-light His paper is especially interesting for the reason that, at the time of writing, the author appears to have been unacquainted with the publications of Yntema, Maurer, and other Europeans on the so-called "earth-light," a brief account of which was published in the SCIENTIFIC AMERICAN Nov 19th, 1910, p 394 Barnard's observations confirm and supplement those of his European confréres

On moonless nights the sky is often more or less distinctly luminous, and this luminosity cannot be wholly attributed to the diffusion of the general starlight by moisture in the air At times the illumination is so great that the face of an ordinary watch can be read by it There seems to be no doubt that this luminosity is of an auroral nature, as it has been shown that the spectrum of the aurora is essentially always present on a clear dark night In describing this phenomenon the author merely corroborates the observations of several earlier writers, but he proceeds to describe a particular manifestation of this luminosity - or possibly a phenomenon distinct therefrom—to which attention does not appear to have been previously directed

This consists of strips and patches of luminous haze, which have been observed at Yerkes Observatory several times during the past year It is not confined to any particular region of the sky nor to any hour of the night It always has a slow drifting motion among the stars, comparable to that of ordinary hazy streaky clouds that are often seen in the daytime The streaks are usually straight and diffused, and as much as 50 degrees or more in length, and 3 degrees to 4 degrees or more in width In some cases they are as bright, or nearly so, as the average portions of the Milky Way, i e, they are decidedly noticeable when one's attention is called to them They are apparently about as transparent as ordinary haze Sometimes, when seen near the horizon, where they may be rather broad, they have strongly suggested the "dawn" or glow that precedes a bright moonrise Their luminosity is uniformly steady

The writer believes this haze to be something quite different from the noctilucent clouds that were seen for several years following the eruption of Krakatoa, but only during the short nights of summer, whereas the haze has been seen through last autumn and winter The noctilucent clouds, with which Jesse's name is always associated on account of his indefatigable study of them were pretty conclusively shown to consist of fine volcanic dust, floating at so great an altitude (upwards of 50 miles) as to receive and reflect the light of the sun long before and after the ordinary clouds Prof Barnard believes what he has seen to be ordinary haze, in some manner rendered self luminous In one instance he watched strips of this luminous substance from before dawn until, as the daylight killed their luminosity, they were seen to be strips of ordinary haze

Meteorologists who read Prof Barnard's paper will undoubtedly be reminded of the references that are occasionally made by students of clouds to "auroral cirrus," for although the author throughout his paper speaks of "haze," he is evidently referring to cirrus or cirrostratus clouds—which are quite distinct from haze in the usual meteorological sense Cirrus seen in the daytime often simulates the forms of the aurora, and that there may be some connection between the two phenomena has often been suggested

A Lake with a Roof

THE great salt lake at Obdorsk is nine miles wide and seventeen miles long, yet except in a few places it is solidly roofed over with a deposit of salt which is becoming thicker and thicker each year

About the middle of the last century salt crystals first began to gather upon the surface of the water Year by year, owing to the evaporation of the water, the crystals became more numerous, and then caked together until this great roof was formed In 1878 the water beneath this salt crystal roof found an underground outlet into the Obi River This covered the lake's surface about three feet leaving that distance between the water and the roof, and each year this distance has been diminished by the constant addition of salt crystals to the roof

Many springs surround this lake Their water flows over the roof and evaporates there and thus continually adds to its thickness After many years the springs will probably become choked with their own deposits, and then the whole will become covered with earth, so that a great salt mine will be formed—a treasure for the Siberians hundreds of years to come

Phases of Science as Other Editors See Them

Studying the Anarchists' Bomb Scientifically

THE bomb laboratory described below is not a place in which bombs are made. No layman has yet penetrated into the secrets of the manufacture of bombs for military use, so that there is nothing to be said on that subject. More is known of bomb factories of another sort, which are operated by criminals, but it is not advisable to describe these establishments, lest the description fall into the hands of some person who might be tempted, either by malice or by simple curiosity, to engage in the manufacture of bombs. The bomb laboratory, the description of which is here quoted from *Reclams Universum*, is operated by the police of Paris for the purpose of investigating and destroying bombs found in the city. It has served as the prototype of similar establishments in other cities.

The progress of chemistry continually makes the path of the transgressor more hard. The slightest trace, even a drop of blood no larger than a pin's head, may suffice to convict a murderer. The impression made on a cartridge by the hammer of a pistol, or a single hair found on the clothing of the suspected person, may serve as valid proof of crime. Until recently, however, science has been almost powerless against the pernicious activity of the bomb-thrower. When a bomb explodes, it is shattered into thousands of minute fragments, and its contents are resolved into gases which cannot be caught and investigated. The effectiveness of bombs depends upon the fact

A bomb with a three-hour fuse.

that they are filled with substances which, when ignited, evolve enormous quantities of gas in a minute fraction of a second. The explosive force of this suddenly evolved mass of gas is enormously increased by the very high temperature to which it is heated by the accompanying chemical reaction. Hence, a bomb which can be carried in the pocket is able to produce terrible devastation.

Nevertheless, the bomb thrower is sadly deceived if he believes that an exploded bomb leaves no trace because its whole contents are converted into gases and because the shell is made of an old gas pipe or tin can, fragments of which would convey no special information leading to the identification of the criminal. It was difficult indeed for chemists to devise methods of discovering the secrets of shattered bombs, but even this difficulty has now been surmounted. This is proved by the recent trial of one of the criminals who attempted to blow up the Municipal Building in Friedberg in order to rob an adjacent bank in the resulting confusion. These same criminals had previously attempted to extort money by threatening letters from a wealthy banker in Frankfurt, and, in order to intimidate him, had placed a bomb in front of his residence. Although the bomb exploded according to the design of the criminals, it nevertheless was the cause of their undoing. The walls of the house were examined very thoroughly, and a few small fragments of the contents of the bomb, which had been thrown out before the flame reached them, were found. These few particles of the explosive mixture, in connection with some other evidence, sufficed to prove with certainty that the bomb had been filled with blasting gelatine. Here was one point gained, and a second resulted from the careful examination of the fragments. Blasting gelatine is made by a great many factories, which differ in their processes and in the composition of their products. It was proved with certainty that the blasting gelatine found in the wall had been made in a factory at Saint Ingbert, from which it had recently been stolen. This was sufficient to identify the criminal completely, because only one person could have been guilty of the theft. In a similar manner the composition of the bomb which exploded in 1907 before the police station in Offenbach

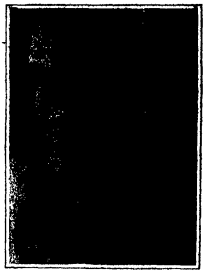
The Paris bomb laboratory.

was determined from a few fragments. In this case a lead tube had been filled with a rather common explosive mixture, but it was found possible to discover not only the character of the mixture, but also the mechanical construction of the bomb.

Very much more dangerous than burst bombs are those which for any reason have failed to explode. Here it is not only necessary to examine the bombs in order to identify the criminal, but it is first of all requisite to make them harmless. This is a rather difficult matter. Some bombs are so constructed that they explode instantly upon the slightest shock or as soon as an attempt is made to disturb their position. The most important of these bombs are those in which the explosion is brought about by means of a liquid contained in a glass tube. The bomb is usually so contrived that the slightest displacement causes a weight to fall upon the tube and break it, so that the liquid escapes and comes in contact with substances which, under its action, explode with great violence. These bombs are perhaps the most dangerous of all, and the methods which are commonly assumed to be proper for the destruction of bombs—immersion in water, for example—are powerless against bombs of this character, which explode in water as well as in air.

Bombs which are exploded by fuse are much less unpleasant to handle, both for the policemen and the bomb throwers, who in many cases have been killed by the premature explosion of bombs of the other type. Usually, however, the glass tube containing the exciting liquid is lowered carefully into the bomb after the latter has been placed in position.

The fuse employed for the ignition of a bomb is usually very long, so that the criminal has plenty of time to escape, and even to accomplish a railway journey of several hours before the bomb explodes. The fuse consists usually of a rain of sulphur or a cord saturated with sulphur. From the time which a measured portion of this cord occupies in burning, the length of fuse required for any desired interval between ignition and explosion can be calculated with accuracy. The bomb shown in the illustration, which



Automobile with a safety bomb carrier.

was found in Paris on a window sill, was provided with a fuse which would have occupied three hours in burning. It would be a great mistake, however, to simply quench or tear out a burning fuse and then freely handle the bomb, for many dynamiters are ingenious enough to attach fuses to the more dangerous bombs of the liquid type in order to mislead the finder in this very way. All bombs, therefore, whether provided with fuses or not should be handled and examined in the careful manner described below.

In the first place, the bomb must be removed safely from the city to the laboratory in the suburbs. For this purpose it is seized with very long tongs of peculiar construction, and slowly and carefully removed, without changing its position with respect to the horizon, from the house or other place in which it is found, to an automobile provided with a safety bomb carrier, which is simply a box supported on gimbals like a compass. Such an arrangement is called a Cardan suspension, from the name of the Italian physicist, Cardono, its alleged inventor. In reality, however, the device was invented by Leonardo da Vinci, as has recently been demonstrated by Dr. Otto Werner. The Cardan or gimbal suspension is used in all cases where it is necessary to keep a body perfectly horizontal. It consists of two concentric rings which can turn on axes lying in the planes of the rings and at right angles to each other. The body to be kept level is attached to the inner ring.

When the bomb has been safely placed in the carrier the most difficult part of the work has been accomplished. The automobile then proceeds very slowly and cautiously to the bomb laboratory, and any small shocks which it experiences are prevented from affecting the bomb by the Cardan suspension.

The bomb laboratory of Paris is situated in the suburb of Vincennes. The bombs are destroyed in a shed constructed of light boards and surrounded by

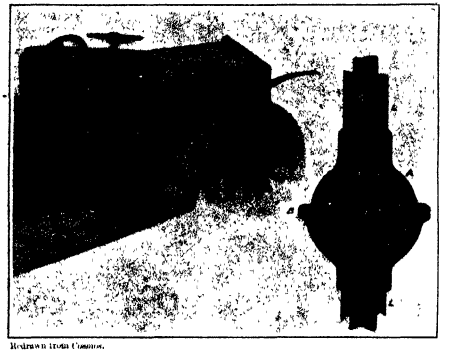
Hydraulic press for crushing bombs.

a wall of earth and an outer and high wall of masonry. If a bomb explodes, the surrounding country, which is a waste and uninhabited land, is thus protected from injury. This precaution is not unnecessary, for stones have been thrown more than a mile by the explosion of a bomb. If the Paris laboratory should be destroyed by a bomb, the light boards would be shattered into still lighter fragments, whose flight would soon be stopped by the resistance of the air. For additional precaution, the building is open at the upper part immediately under the roof, so that the pressure of the exploding gases cannot become very great. The shed is also surrounded by a board fence, at one corner of which stands a sentry box which is always manned. Inside of the fence and outside of the earth wall is situated a workroom containing a collection of bombs and fragments of bombs, with apparatus for the examination of bombs. Here, also, is the pump cylinder of a hydraulic press which is connected by a subterranean tube with the press cylinder in the bomb shed, inside the earth wall. The bomb is removed from the automobile with the greatest care and placed upon the piston of the press and below the fixed headpiece. The men then retire to the outer workroom and the press is set into operation. As the piston rises the bomb is crushed. It has been proved by experience that the safest method of opening bombs is by crushing in this manner because all parts of the bomb are left undisturbed, and because the shell is usually cracked before the glass tube is broken. If an explosion occurs the gases can escape through the broken shell without doing much damage, as they encounter little resistance at this point or in the open shed, so that the contents of the bomb are quietly consumed, leaving sufficient traces for the determination of the composition of the mixture.

It is evident from this description that the struggle between the chemist and the dynamiter is not without interest, and that it is waged with modern weapons in

the full sense of the word, despite the employment of the rather crude, mechanical aids which have been described. It is especially gratifying to find that in this difficult field the criminal has been conquered by science.

A Flexible Steering Column for Automobiles



WITH the low and elongated automobile bodies that have recently come into favor the steering column is necessarily placed in a very oblique position. This construction is both inconvenient and dangerous, for when the driver has insinuated himself into the narrow space between the steering column and the seat he is completely imprisoned and immobilized by these parts, by the levers at his right and by the passenger at his left, whom he must disturb in order to leave his seat. If the car is suddenly stopped by a collision, the driver is projected violently forward and is seriously injured by the steering wheel

A French inventor named Martinot has patented a steering column which can be bent forward sufficiently to permit the driver to mount and dismount easily, even on the right side, and which bends forward automatically in case of sudden stoppage, so that the driver is thrown clear of the car, instead of being crushed by the steering wheel. The description and illustrations of the apparatus which are here given are taken from a recent issue of *Cosmos*.

The steering column is made in two parts, *MM*, which are connected by a universal joint *I* (Fig. 1), of simple and massive construction, which does not impair the strength of the column. The movement of the upper part of the column is confined to a fore-and-aft vertical plane by two hemispheres *AA'*, which are attached respectively to the tubes *L* and L_1 inclosing the fixed and movable parts of the column, and which together form a hinge joint, turning on the axis at *B'*. The fixed and movable parts of the column are securely fastened to the cross of the universal joint by pins, in addition to the screw-bolts *GF*, etc.

The two extreme positions of the steering column are shown in **Fig. 2**. The angle of displacement is limited by a stop, which is adjusted in accordance with the space available in each vehicle. The movable part, in consequence of its weight, naturally assumes the normal position, in line with the fixed part, and the pressure exerted on the wheel by the driver's hands, tends to hold it firmly in this position. The inventor claims that the wheel cannot be thrown forward by vibrations of the car or inequalities of the road, even at the highest speed.

As the two parts of the column, however, are connected by a universal joint, the apparatus works perfectly in any position. It may, therefore, be modified by the addition of a second stop so that the two parts of the column are never in line, but form with each other, even in steering, an angle determined by the convenience and preference of the driver.

Redrawn from Cosmos.

FLEXIBLE STEERING COLUMN FOR AUTOMOBILES

Why Europe Is in Advance of America in Pioneer Inventions

THE discussion which was recently started in the columns of *Engineering News* on the subject of Europe's superiority in the matter of pioneer inventions has called forth, among other letters to the editor of that journal, one from Mr. George H Gibson, which should be illuminating and highly instructive to readers of the SCIENTIFIC AMERICAN.

Mr. Gibson says, very truthfully to our mind, that "while most American manufacturers are aware that the profits of engineering lie in pioneer work, not all of them as yet understand the proper utilization and management of research. The demand for research is not brisk over here and the schools have done little either to excite it or to turn out men properly qualified to fill the demand if such should arise. Possibly as an incident of rapid commercial expansion, engineering enterprises are generally controlled by business men, rather than by directing engineers, while the technician is a subordinate employee, who receives little encouragement or aid toward the initiation, planning or carrying out of sustained investigations."

In Europe, Mr. Gibson assures us, the situation is different. "The engineer or scientist frequently occupies a more independent position. I am told, for example, that Prof. Rateau, who has developed many lines of centrifugal machinery, including steam turbines, centrifugal pumps, air compressors, blowers, etc., becomes various concerns in France, Germany and elsewhere, that is, his rights are not assigned *in toto* to some corporation, as would probably happen in America.

"Similarly the professors in the leading German technical schools, in addition to teaching, maintain large engineering offices, in which research and experimental development work is prosecuted on an extensive scale. The remuneration received from their inventions and for their engineering work enables these scientific engineers to maintain large staffs, while their connection with the laboratories and the other facilities of educational institutions naturally leads to the full utilisation of the resources of scientific knowledge and methods"

Pure Food and What It Means

IF so much of our lives and so much of man's ambition are bound up in the great problem "What to Eat and How to Get It," we surely do well to consider what manner of food we are getting in return for life's struggle, whether, in a word, it is pure, clean and wholesome; whether it is calculated to give us the sustenance and strength, the health and prolongation of life that we have a right to expect, or whether it is sometimes so far a mixture of bad with the good, that almost literally we are given a stone when we ask for bread.

This whole question was ably considered by Mr L. S. Dow, before a meeting of the Section of Physics and Chemistry of the Franklin Institute His paper on the subject is here abstracted from the journal of the Institute

"The rapid growth of the preserving business in its early stages attracted much capital without corresponding experience, and in such cases, for the most part, business disaster was only averted by the extensive employment, in nearly everything produced, of chemical anti-ferments, which served as a protection against all the mistakes of cooking, sealing, and sterilization, and obviated entirely the necessity of proper sanitation either in methods or surroundings. The first objection to their use, however, and, I believe the most glaring abuse that exists to-day, lies in the employment for the purpose of preserving partly spoiled and ill-cared-for vegetables and fruits The principal substance that is used for the artificial preservation of vegetable and fruit products, as well as for meats and fish in some cases, is the drug benzoate of soda—which, in its least objectionable form, is a tasteless and odorless derivative of coal-tar.

"It is not my purpose to discuss here the extent to which the substance, sodium benzoate, itself may be harmful. That is a scientific question, the discussion of which I am willing to leave to scientific men, confining myself rather to a few brief words concerning its possible significance in food products But, before proceeding to this phase of the artificial preservative question, I would like to call attention to the fact that the weight of scientific evidence, especially on the part of the medical profession, is strongly opposed to it, and to suggest that if there is a doubt about the amount of injury that it causes, the people, and not the manufacturing interests who desire to continue its use as a means of securing a greater pecuniary profit, should have the benefit of that doubt"

Mr. Dow states that every product of fruit and vegetables with which he is familiar can be successfully made in a commercial way without artificial preservatives, which statement he considers demonstrated because the entire product of at least twenty-five, and probably more, leading American food preservers is entirely free from these substances. "Why, then," asks Mr. Dow, "should any one wish to continue their use? Commercial cupidity yields very grudgingly to attempted reform There is cannery waste to be worked up profitably into ketchups and soups—skins, cores, and decayed parts of tomatoes, cooked up and thrown into barrels to be shipped about the country for use as wanted There are always job lots of spoiled or partly spoiled fruits and other similar materials lying about in the season that can be picked up cheaply To say nothing of the expense attending its proper disposal, it is hard to send such material to the sewer when profit can be gained from it by sufficiently dosing it with a chemical preservative to protect it from putrid fermentation, and then disguising its taint with spices and flavors until it really becomes quite presentable and, in a degree, acceptable to those who do not discriminate very closely in favor of quality, and who are only slowly learning the significance of the legend on the outside of a package 'Preserved with one-tenth of one per cent of benzoate of soda'

"While the demand of the reactionary manufacturer for the continued tolerance of some kind of an artificial preservative is based upon several reasons, the principal pressure in its favor comes from users of tomato waste, which has a commercial importance not generally understood Tomatoes are probably more extensively canned than all other summer vegetables put together—and all the canning is done in a period of six to eight weeks, under high pressure Tomatoes are also more extensively used in soups, condiments, sauces, etc., than any other fruit or vegetable—the consumption of tomato ketchup alone running into many millions of dozens annually"

Mr Dow draws a picture of skins, cores and decayed tomatoes, which there is neither time nor inclination to care for, falling under foot and disregarded as it accumulates Hundreds of thousands of barrels of this refuse, he assures us, are sold in a season

"It is pulped and put into the barrels under conditions that would better be left to the imagination than described, and then chemically 'preserved' against actual putridity It is safe to say that no one would ever again desire to eat any benzoated article after once seeing this material and its treatment

"This tomato refuse is sold at about $1 00 to $4 00 per barrel, to be made into tomato-ketchup soup, baked-bean sauce, etc., which are eventually labelled as made of fresh, ripe tomatoes, and which carry only one protection to the consumer—namely, a statement of the presence of the preservative on every label, which is put there under one of the occasional beneficent food regulations of the Agricultural Department at Washington, but it is always printed as small and obscurely as possible Thus the consumers' only protection is to read all food labels carefully, including the fine print"

Mr Dow states that it is really around the tomato waste industry that has rallied most of the effort for nullification of the Pure Food Provisions of the National Food and Drugs Act

A term much employed by the pro-preservative interests in their defence is "concealed inferiority," the contention being that the addition of a chemical preservative to rotten tomatoes or fruit, for instance, changes neither the odor nor flavor of the material Unfortunately for this line of argument, nobody contends, or ever has contended, that benzoate of soda "conceals inferiority" "The expression 'concealed inferiority" is simply one coined as a premise upon which to build false argument Artificial preservatives do not conceal inferiority, but they do permit and encourage disguised inferiority and the grossest fraud

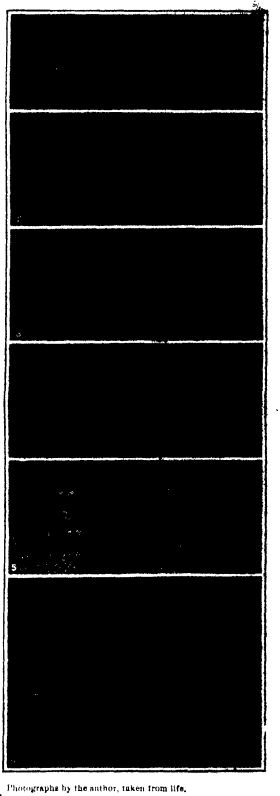
In order to cheapen the product, Mr Dow states that many manufacturers retain as much water as they may find convenient Bottles and other containers need not be washed, and sterilization becomes a useless expense

"I have no hesitation in saying that the principal use of benzoate of soda and like substances in modern food manufacture to-day is either to permit the use of a lower grade of material, or carelessness in process. Its tendency is to lower quality in some direction all the time, and to invite actually unwholesome practices, and the question of whether we are to have cheapness in our foods at the expense of quality and wholesomeness is as much alive to-day as it was before a food law was placed on the statute books."

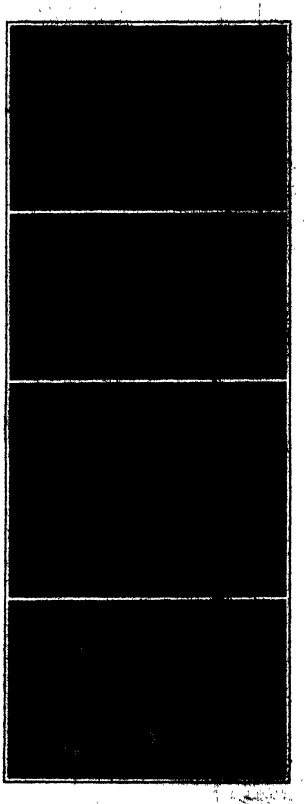
The Original Paper Makers

The Paper Wasp and Its Life from Egg Until Death

By Paul Griswold Howes



THE communities of the paper wasp, like those of other social insects of the family, consist of three kinds of individuals—males, females and workers. The colonies only exist for a single season, the males and workers dying in the fall. The females or queens hibernate and each starts a new community in the spring. The queen is the largest in the colony and her one duty, after the first few weeks of spring, is egg laying. The males or drones are created for the one purpose of fertilizing the eggs of the queen and after performing this duty they are frequently killed and thrown from the nest by the workers. These so-called workers are in reality undeveloped females who are unable to reproduce in a beneficial way, as their eggs invariably produce drones. Thus they are unable to assist in increasing the numbers of working individuals in the colony and the heavier work must therefore fall upon these otherwise useless members.



Let us start with the queen mother, the only survivor of last year's colony who has safely passed through the winter in an impregnated and torpid condition and who must now lay the foundations of another great insect city.

When in the spring she lays the first foundations of her future empire, she has not a single worker at her disposal, and with her own hands and teeth she must hollow out a tiny cave wherein to lay the corner stone of her future metropolis. She must herself build the first combs and produce from her own body their first inhabitants, which in their infant state she must feed and educate before they can assist her in the great design. At length she receives the reward for her perseverance and labor, and from being a solitary unconnected individual, in the summer is enabled to rival the queen who gave her birth, in the number of her children and subjects and in the empire of which they are inhabitants. Each at this time, when she has so numerous an army of coadjutresses, the industry of this creature does not cease, but she continues to set an example of diligence to the rest of the colony. If in any way the queen mother perishes before the other females are hatched, the workers lose their instincts, cease their labors and die.

The number of females in a wasp colony is very considerable. They are hatched about the latter part of July or during the first part of August, at the same time and in about the same numbers as the males. In September and October they fly from the nest and after mating the males live but a short time. Of all the females, few survive the winter to start the new empires when the vernal sun brings the insect world to life again.

To the workers falls the entire care of the young and other members of the colony. They must not only supply the food, which consists of honey and chewed up insects, but they must also protect the nest from outside intruders. These poor "Neuters" must also be ready and willing at any time to do construction work upon the rapidly growing nest. Almost daily there are new cells to be built, walls to be strengthened, openings to be closed and all manner of things which only a worker can do. Of all these operations, no other is so interesting as the process by which the wasp's paper is made. It is, of course, manufactured from wood pulp which is scraped by the worker from old boards, fence rails and other unpainted lumber which has been well weathered for two or three years. These tiny particles of wood fiber are mixed by the wasp with a glutinous substance of some sort which is apparently spit up by the worker herself. Now she rolls the whole mass between her fore feet until a small gray pellet has been formed, and with this she flies to the nest. The pellet is then dropped in the proper place and left until the edge of it adheres to the edge of the cell next to which the new one is to be constructed. When this has been accomplished, the insect draws the pulp from a ball or pellet into a long thin line

The nest two months old, showing broken cell ears through which the young wasps have hatched. 5. Worker wasps strengthening the central stem which supports the nest. 6. Six months old nest, and its inhabitants dead. 7. Hibernating queens. 8. A warm day in winter brings the torpid wasps to life; the two in the upper left-hand corner are communicating with their crossed feelers. 9. Section of "nipe rail, showing (at the bottom on the right-hand corner) gouges made by paper wasp in collecting wood fiber for pulp. 10. Young paper wasps in the pupal stage.

THE ORIGINAL PAPER MAKERS

body of the young wasp. There it lives feeding upon the body of its host during its hypermetamorphosis. If it is to be a male, it transforms into a chrysalis and soon after this hatches out from the body of the young wasp to live its short adult life, which lasts fifteen minutes to three days. If a female it never turns into a chrysalis, but when the maggot host itself changes into one, the apparently immature Xenos pushes one end of its body out between two of the host's abdominal segments, and there, unlike the female of any other insect family, gives birth alive to a great many tiny beetles in the earliest and most undeveloped stage of their lives.

Owing to the position of the comb, when the young wasp hatches it is suspended head downward in the cell. By means of a glutinous substance (probably the same as the older wasps possess) the larva, as the young one is called, manages to bend itself in place until its head grows long enough to fill the sealing down end. When the larva becomes full grown it spins a cocoon of whitish silk, the bottom of which serves as a cap stone to the cell. In this position the young wasp transforms into a pupa or chrysalis and it is then helpless until the time when it issues as a perfect insect. After this event the cell is cleaned out by the workers and used over again by the queen. The whole period required for the transformation, from the time when the egg is laid until the full grown wasp issues from its cocoon, is about four weeks; thus it will be seen that the same cells may be used many times during a single season.

The last brood of the year consists mostly of queens and drones and after these have been hatched the workers of the colony soon die. The inside of the cells may then be found to contain curious brownish skins, cast off by the chrysalis and which the workers did not have time to remove before the cold weather arrived.

Unlike the large globular nests of the hornets, those of the paper wasps are simply a mass of uncovered cells, ranging in numbers from fifty to five hundred. These are suspended by a single central stem from the under sides of large overhanging stones or from beams in old barns and sheds.

These insects are undoubtedly beneficial from the fact that they have been known to prey upon the destructive rubbage caterpillar in the vicinity of Washington and also in Connecticut. Howard in his Insect Book describes their actions as follows: "The wasps would hover above a plant and then alight and walk about it, but finding nothing, would continue to the next plant and so on to the next. In the sunny center part of the field the cabbage caterpillars were exterminated, but in the shady portions next to a patch of woods, they were present in great numbers. Wasps do not see small objects clearly. They find their prey more by sense of touch than by sense of sight, and as they prefer the sunshine they unconsciously ignored the abundant caterpillars in the shade."

Kirby has left us the following extraordinary account of the manner in which the workers care for the young and helpless members of the community. These observations apply to the common yellow jacket or hornet, but many of the statements hold true in the case of the paper wasps although I have not as yet been able to verify them all. Wild colonies are the most interesting, and the only feasible way to observe them is [illegible]

to the opposite side of the nest. From here she goes back to the start, and places her tong-like jaws over the paper thread, closes them, and simply walks backward away from the point of contact, and thus flattening it into a long gray ribbon which is easily shaped into a low hexagonal cell.

In this manner several layers of paper ribbon are applied, each layer above the other, until the cell is of the proper depth. It is then ready for the delicate white egg which the queen lays almost at its very bottom. The egg is fastened to the paper wall by the same glutinous substance which holds the nest together, and it is almost impossible to remove it without leaving a portion of its tender shell adhering to the wall within the cell.

In the course of a few days the eggs hatch out into soft footless maggots, and it is at this period of their lives that they are subject to the attacks of a very curious beetle parasite called the Xenos. The young of this insect is a tiny active creature which burrows into the

The Home Laboratory

[The Editor of the Home Laboratory will be glad to receive any suggestions for this department and will pay for them, promptly, if available.]

Simple Electric Furnace

By C. C. Kipfinger

THE furnace herewith described was made out of three fire-clay bricks, two three-fourths inch arc-light carbons, a piece of large rubber tubing, a short length of hoop iron, and a bolt. In less than two hours from the time the materials were collected, the apparatus was in good running order.

Fig. 1.—The furnace dismantled.

Fig. 1 shows the various parts before assembling. Two of the bricks have one edge beveled as shown, by means of light blows of a hammer and cold chisel, so that when placed face to face, with the latter edges adjacent, a V-shaped trough is formed. This trough should be of such size that, when the cartons are laid in it, the third brick, which forms the cover, will rest flatly on the sides of the other two. The carbons should fit closely, but not tightly, the cover brick holding them in place. A shallow groove is cut in one of the bevel bricks, at right angles to the trough, leading to the exterior of the furnace. This affords a means of examining the interior during the combustion

A piece of hoop iron, or band iron, is bent so as to form a rectangle which fits the base of the furnace closely. Holes are punched in the ends of the iron and a bolt passing through these affords a means of tightening this binding device. If more convenient, the two bricks may be bound together with heavy iron wire.

The furnace as assembled is shown in Fig. 2. The carbons should be copper plated and have the connections soldered to them, although unplated ones may be used. A short piece of heavy rubber tubing is slipped over the end of each carbon to form an insulating handle, by means of which it may be adjusted with safety. If so desired, a small piece of mica bent at right angles may be used to cover the side opening of the furnace. A delivery tube may be inserted in this aperture, and the volatile products of

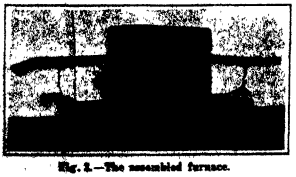

Fig. 2.—The assembled furnace.

the combustion withdrawn by aspiration, for the purpose of their study. Fig. 3 shows the furnace in operation, a spectroscope being used in connection with it as a means of investigating the chemical changes taking place.

It may be found necessary to use a resistance in connection with the instrument. An unplated arc-light carbon makes a very good and cheap one. A resistance is shown in Fig. 3, resting on the sheet of paper at the foot of the furnace. Double brass clips, such as are used in photography to hang prints and films to dry, make very good substitutes for binding posts in this, as well as in other electrical work. The current which is used in the original of this apparatus is 104 volts, 15 amperes, alternating.

The chief merits of the above design are its adaptability, cheapness, ease of construction, and the facility with which it may be cleaned and repaired. Fire bricks can be obtained at almost any furnace room. The capacity of this furnace is small, but the reactions are characteristic. Moreover, it may be used either as an arc or as a resistance furnace For special operations, it may easily be made air tight with a little thick fire-clay, or ordinary clay mortar. The latter

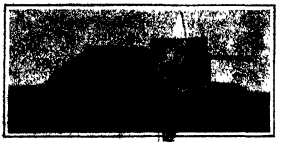

Fig. 3.—Furnace with spectroscope attached.

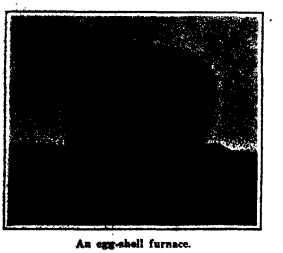


may also be used to repair defects which may develop with continued use.

Calcium carbide, a typical high temperature product, may be made by finely pulverizing three parts by weight of unslaked lime, together with two parts of coal, and subjecting this mixture for an hour to the action of the arc. Many other interesting processes may be imitated on a small scale, and research work carried on with a high degree of satisfaction

An Experiment with Aluminium Powder

By Gustave Michaud, Costa Rica College

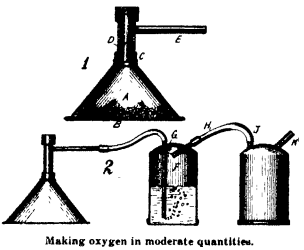
THE enormous amount of heat evolved during the combustion of aluminium has been applied, in recent years, to several industrial operations The following easily performed experiment shows in a striking manner the possibilities of the new thermic agent. The amateur is warned, however, that the mixture is highly explosive and must be handled with care, preferably in the open, out-of-doors.

An egg-shell furnace.

Most people would think that the melting of a large gold or silver coin requires some pounds of coal, a furnace and some time The idea is not unreasonable, as gold melts at 1,064 deg C and silver at 960 deg C As a matter of fact, however, a silver quarter can be changed within a few seconds into a liquid sphere with the amount of combustible contained in one half of an egg shell, and in a furnace which is the egg shell itself, no blast whatever being used The feat requires the use of the following mixture

Aluminium powder	17
Flowers of sulphur	15
Saw dust	16
Potassium nitrate	52
	100

The saw dust and the powdered potassium nitrate are dried separately on the kitchen stove When cold they are mixed with the other two ingredients. The mixture is then compressed into one half of a dry egg shell. The silver quarter is laid over it, as shown in the accompanying figure, and a match is applied to the composition. The molten silver coin always collects itself into one single lump, which remains highly luminous some time after the combustion is over.



Making Oxygen in Moderate Quantities

By A. J. Jarman

THE experimental production of oxygen upon a small scale with a test tube or glass retort is very useful in demonstrating a chemical point, where only a small quantity of oxygen is needed. When a larger quantity of this gas is required to fill a dozen large vessels or more, for lecture purposes, or for use with the oxyhydrogen blowpipe, for the fusing of metals and other refractory bodies, then resort must be had to a more substantial type of generator The type of retort and the wash bottles here described have been used by the writer for several years successfully, particularly for the production of oxygen for limelight, for stereopticon and dissolving view apparatus, and for lecture room demonstration

There are many handy men who will be able to make both the retort and the wash bottles, these latter being made of zinc Fig 1 shows the body of the retort, which is made of moderately stout sheet iron, with a flange bent outward at the bottom *B* represents the bottom, made of sheet copper The flange of the iron cone being filed clean, the copper is beaten over this flange, then brazed all around in a blacksmith's fire with spelter, using borax for the flux The screw socket at *C* consists simply of an ordinary iron pipe socket, such as is used for connecting wrought iron gas pipe This is also spelter brazed into the top of the cone *D* is a piece of iron gas pipe of one-inch bore, with a screw cap at the top, and *E* is a piece of three-eighths inch bore iron pipe, with a screw at one end, so as to fit into a hole that has been tapped to receive it at the top of *D* This outlet pipe also answers the purpose of a handle for removing *D*, so as to place the charge in the retort, as well as acting as a lever to screw the joint quite tight to prevent the escape of oxygen Fig 2 shows the arrangement of retort and wash bottles when in action generating oxygen The advantage of this kind of retort is that it will resist almost any amount of wear and rough usage At *F* in Fig 2 is one of the wash bottles in section, showing the oxygen passing down the inlet pipe at *G* and through the outlet pipe at *H*, then down the inlet pipe at *J* of the second wash bottle, thence out at *K*, to the receptacle, which may be either a metal gas holder or an India rubber gas bag These inlet and outlet pipes are simply made of the ordinary composition metal gas tubing firmly soldered into the zinc bottles The connecting tube is a good quality of vulcanized India rubber Each of the bottles should hold about three pints

To prepare the oxygen mix one pound and a half

Making oxygen in moderate quantities.

of potassium chlorate in crystals, and half a pound of peroxide of manganese (the ordinary black oxide manganese) The use of the manganese prevents the chlorate from fusing into a mass and aids the production of oxygen The wash bottles must be charged with a pint and a half of cold water The object of this is to absorb and retain any trace of chlorine that might pass over in case the retort became over-heated, and to cool the gas The quantity of potassium chlorate here given will produce well over six cubic feet of pure oxygen—in fact, enough to allow of some waste, which is sure to take place in preparing this gas unless exceptional care is taken As soon as the gas ceases to be evolved, disconnect the tubing, remove the retort from the fire or gas stove, place it upon the ground or stone floor, press one foot upon the side of the cone, give the tube *E* a sharp rap with a hammer, this will start the screwed joint; remove *D* entirely and pour a pint of water (no matter whether it is hot or cold) into the hot retort This will loosen the contents quickly The retort should be well washed out and dried, so as to be ready for future use The water in the wash bottles must be poured off, and the bottles allowed to drain For those who wish to prepare their own oxygen, the following facts may prove useful Eight ounces of potassium chlorate will make, under ordinary circumstances, rather more than two cubic feet of oxygen The chlorate may vary a little in quality, but for all practical purposes these figures will supply the necessary information. Those who wish the information a little more accurate for making oxygen on a small scale will find that one hundred grains of pure potassium chlorate will yield one hundred and eight cubic inches of pure oxygen There are many other chemicals that will yield oxygen upon heating, but there is nothing that will surpass the potassium chlorate and peroxide of manganese mixture.

The Heavens in August

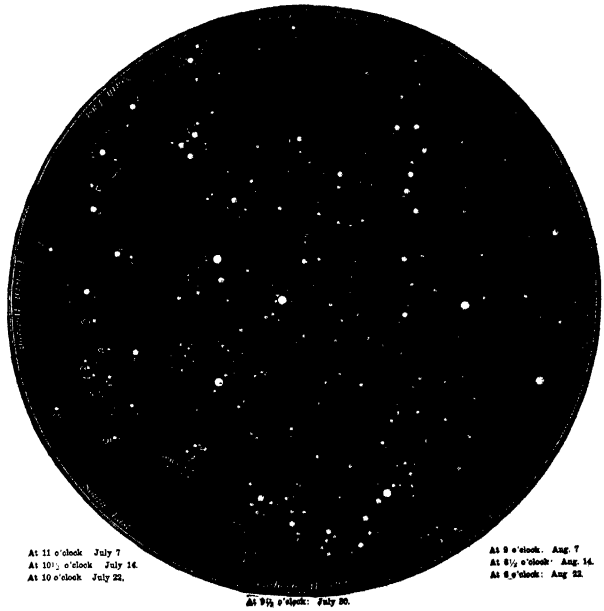
The Brightest Stars of the Month; The Aberration of Light; The Planets; The New Comet

By Henry Norris Russell, Ph.D.

VER our heads, as we look up on a clear August evening, shines a very bright bluish-white star Even a novice in star-gazing will recognize this as **Vega**, the principal star of the constellation Lyra, and, according to the careful measures made at Harvard, the brightest in the northern heavens

For the latter honor it has, indeed, two close rivals, Capella being but seven per cent fainter, and Arcturus ten per cent The very marked differences in color between these stars introduce great difficulties in such a comparison The eyes of different persons are unequally sensitive to light of different colors and an observer who was unusually sensitive to red light would undoubtedly estimate Arcturus to be brighter than Vega In making the comparison it is necessary to choose a time when the two stars are equally high above the horizon, for otherwise the absorption of light in our atmosphere, even in clear weather, makes the star lower down seem the fainter

On photographs, which are far more sensitive than the eye to the blue and violet rays, Vega appears nearly twice as bright as Capella, and fully three times as bright as Arcturus.



Three stars in the southern half of the heavens—Sirius, Canopus and Alpha Centuri — exceed Vega in apparent brightness, but only the first is visible in our latitude Measures of parallax show that Vega is four times as far away as Sirius so that as a matter of fact it exceeds the latter about three-fold in real brightness

Telescopically, it is interesting because of its great brilliancy, and on account of a faint companion, some 40 seconds distant, which does not share the motion of the bright star, and presumably lies far behind it As our initial shows, Lyra is one more example of a constellation wholly unlike the thing for which it is named Though it boasts no other bright stars, it contains several objects of interest Close to Vega are two small stars, forming with it a nearly equilateral triangle The northernmost of these, Epsilon Lyrae, is just separable by a keen eye, and easily divided by an opera glass A telescope of three inches' aperture will show both components of this wide pair as close doubles, forming a splendid quadruple system The two close pairs are in slow orbital motion, and all four stars are moving together in space

The other star of the triangle, Zeta Lyrae, is a wide telescope double, with separation of 43 seconds A line from Vega through this star carried as far again points out Delta Lyrae—a very wide pair, separated by ten minutes of arc, which is pretty in a field glass Some five degrees to the southwest are the brighter stars Beta and Gamma Lyrae The former (which is nearest Vega) is a remarkable variable and spectroscopic double, consisting of two unequally bright stars revolving almost in contact in a period a little less than thirteen days, which mutually eclipse one another The closeness of positions very a good comparison star makes the variation equal in easy to follow At maximum it is nearly brightness to Gamma Lyrae; at minimum less than half as bright. Almost on the line joining these two stars is the Ring Nebula of Lyra—a beautiful object in a telescope of sufficient power.

Not far from Lyra, and just north of the zenith, is the head of Draco, marked by two bright stars, of between the second and third magnitudes. The easterly one of these, Gamma Draconis, is of considerable interest in the history of astronomy, since it was by observing it that the great English astronomer Bradley, early in the eighteenth century, made the important discovery of the aberration of light.

Bradley's original purpose was to observe the position of this star in the heavens, with an instrument of his own invention, much superior in accuracy to those previously used, in the hope of detecting a yearly change in its position, due to the earth's orbital motion about the sun—in other words, what we now call an annual parallax.

NIGHT SKY: JULY AND AUGUST

If such an effect of the earth's motion should exist, it is clear that the star should appear farther south than usual when the earth was north of the sun (as seen from the star) and farther north than usual when the earth was south of the sun (or the sun north of the earth, which happens in June).

But the actual observations showed a different and very perplexing state of things. The star's apparent position changed, but it was farthest north, not in June, as apparently it ought to have been, but in September—three months late! In June and December, when the effect of parallax should be a maximum, the star's position was almost exactly the same, but between September and March, when no difference owing to parallax could be expected, a large difference was actually observed.

After much puzzling over this strange phenomenon, the true explanation occurred to Bradley while sailing on the Thames, upon noticing that the wind appeared to change in direction every time the boat tacked and changed her course.

Suppose the wind to be blowing from the north, as observed on shore, or on a vessel at anchor. Now suppose the ship to get under way, and proceed due east. In a calm this would apparently produce, for an observer on board, a wind blowing from the direction in which the vessel was heading. The combination of this with the actual north wind would make the wind appear to come from some point east of north. The faster the ship's motion, compared with that of the wind, the greater would be the deviation of its apparent direction.

Now suppose the ship turned about and headed due west. The wind would now seem to come from a point as far west of north as the direction previously observed was east of north. But if the ship was steering north or south, the apparent direction of the wind would be unchanged, though its velocity would seem to be increased or diminished.

Now the light which reaches us from a star, though in other respects quite unlike wind, possesses like the wind a finite velocity; and the combination of this with the velocity of the observer, who is carried along on the moving earth, produces similar effects. When the earth is moving in any given direction — say northward—the light of a star which is not in the line of motion will seem to come from a point farther north than its true position; that is, the star will apparently be displaced to the northward, and *vice versa* if the earth is moving southward.

Now this is exactly what Bradley had observed—the star being apparently farthest north just at the time when the earth is moving northward fastest—or the sun apparently moving southward at the most rapid rate. This occurs in September and all the other observations are equally well explained.

The mystery was thus cleared up. What is more, a conclusive proof had been given that the earth is not fixed in space, but moves around the sun

The rest of Draco winds about, first to the right, then to the left and downward, inclosing Ursa Minor and separating it from the Great Bear, which is descending in the northwestern sky. On the other side of the Pole, Cassiopeia is rising and Cepheus is higher up. Following the Milky Way southward, we reach Cygnus, and then Aquila, in the southeast. The great square of Pegasus has just risen and the line of stars which runs from it through Andromeda and Perseus is near the northeastern horizon. The lower southeastern sky is dull, containing only Capricornus and Aquarius, but the region of Sagittarius and Scorpio, in the south, is one of the finest in the heavens, and contains the brighest part of the whole Milky Way.

Spica Virginis is low in the southwest and much less conspicuous than the planet Jupiter, which is a little to the left. Libra, Ophiuchus and Serpens fill a large area of the southwestern sky. Hercules is west of the zenith, Corona Borealis below, and Bootes lower still, Arcturus being almost due west of the zenith.

THE PLANETS.

Mercury is evening star throughout August, and is best visible before the 12th. His apparent distance from the sun (27 degrees) is unusually large, but, being far south of the latter, he remains in sight for only an hour after sunset and will not be easy to see. Conditions will be most favorable in the early part of

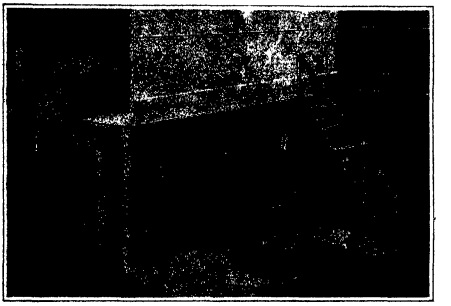
Alexander Graham Bell's Ice Stove

A FEW weeks ago we published an article by Mr. W. A. Dupuy on Alexander Graham Bell's ice stove. One of our subscribers has suggested that we publish a picture of the arrangement, so that others may profit by Dr. Bell's ingenuity. The accompanying engraving is the result.

As our readers will remember, Dr. Bell converted his swimming pool into a study and living room. Pipe *A* discharges at *A'* cold air from an ice-box *B* into the lower portion of the swimming pool. In the pipe *A* is placed an electrically operated fan *C*, which receives the air from the ice box *B*, which may be an ordinary ice box, and the air in the pipe *D* leading to the box *B* for supplying fresh air has a suitable valve *E*, by which the supply of fresh air may be regulated. The drawing shows the ice box in a small room adjoining the swimming pool

A Small Portable Ice Machine



THE modern tendency is toward large scale production. The spinning-wheel may be seen in our homes as an heirloom, but it is silent and unproductive. We find it cheaper and better to have our industries concentrated in large factories, which turn out our clothing, our prepared foods, our ice and what not in bulk. Nevertheless, home "manufactures" have not yet quite passed away, and naturally they too have been modernized by calling to aid the various resources which the development of mechanical and other arts place at our disposal. An instance in point is the ice-making machine shown in our accompanying illustration. This depends for its action upon the well-known fact, that a liquid in evaporating absorbs from its surroundings a certain quantity of heat, commonly termed the "latent heat of evaporation," thereby cooling those surroundings. In order to apply this fact to practical advantage, we need a container from which a suitable liquid, such as water, is evaporated, an air pump wherewith to reduce the pressure above the liquid, so as to cause its evaporation at low temperatures, and finally some absorbent to take up the vapor, and assist in maintaining a low pressure in the apparatus Referring to our illustration, the rotary pump will be seen at the rear on the left, connected by a ruffer suction pipe to the "absorber." This latter is simply a glass vessel containing commercial concentrated sulphuric acid, which should be free from hydrochloric acid. The purpose of the sulphuric acid is to take up the vapor evolved from the water placed in the vessel (a carafe in our drawing) which is being cooled. This vessel is connected to the absorber by an enamelware tube with rubber ends. A block of ice may thus be formed directly in a carafe of table-water, or a suitable wide-mouthed vessel with adaptable cover may be substituted for the carafe, and any material, such as ice-cream mixture for example, can be frozen.

The Ventilation of Sleeping Cars

WHEN Dr. Lorenz, the famous orthopaedic surgeon, was in this country some years ago, he expressed his astonishment that so ingenious and inventive a people should tolerate such an unsanitary abomination as the type of sleeping car used on American railways.

What Dr. Lorenz complained of particularly was the lack of ventilation. That subject was ably discussed in a paper by Dr. Thomas R. Crowder, which was read before the annual meeting of the American Public Health Association. Apparently, the ideas of Dr. Lorenz are all wrong.

Dr. Crowder says: "According to the older theories, the sensations of discomfort arising in inclosed spaces had their origin either in an excess of carbon dioxid or an insufficiency of oxygen. Pettenkofer cast the first serious doubt on the correctness of these theories. Hermans proved

How Dr. Alexander Graham Bell keeps cool in hot weather.

that air containing 15 per cent oxygen may contain 2 to 4 per cent carbon dioxid and not be harmful. On removing the carbon dioxid there was no great discomfort even when the oxygen was reduced to 10 per cent.

"It seems to be established beyond reasonable doubt that discomfort is not due to any change in the chemical composition of the air, but to physical changes only; and that to maintain a normal heat interchange between the body and the air is to avoid the development of those symptoms which are commonly attributed to poor ventilation. A certain amount of fresh air must be supplied, of course, but the most vital element of the ventilation problem becomes that of regulating the temperature of the air. The question of how to ventilate a railway car is therefore chiefly a question of how to regulate its heat."

In cars which are close or stuffy, Dr Crowder says, the temperature is invariably high What is more, a high temperature renders odors more noticeable. The most marked offensiveness that he had ever noticed was in a day coach, where the air was in such a degree of chemical purity as to indicate ideal ventilation by any standard that has ever been proposed

A small vacuum ice machine.

The car was hot and many filthy people in it On the other hand, with perfect comfort has been sometimes associated the highest chemical impurity

"It seems probable, furthermore, that one main cause of the complaint of poor ventilation in the sleeping-car berth is purely psychic We are used to sleeping-rooms with walls and ceilings far from us In the berth they are very close Their very nearness is oppressive It seems as if there cannot be enough air in this small space to supply our wants The sensation is often quite independent of the amount of air supplied and even of the temperature.

"Even under the older applied principles of ventilation, the air-supply of sleeping-cars, as determined in this study, is ample under nearly all conditions. The average carbon dioxid in the air of running cars falls well within the limits of contamination permitted by the earlier investigators, and it is relatively rare that the individual observations show more than 10 parts in 10,000. In the light of the newer conceptions, which have as yet been applied in practice only to a very limited extent, this air-supply is ample under all conditions observed. No danger to health is to be apprehended under the conditions ordinarily obtaining even in still cars They are occupied only for short periods as a rule and are not uncomfortable if kept cool"

In Dr Crowder's opinion, "the results obtained by the type of exhaust ventilator which is now a part of the standard equipment of the Pullman cars, are entirely adequate to meet the demands of hygiene, and that those difficulties and discomforts which do sometimes arise are due to other causes than lack of a sufficient amount of fresh air or to excessive vitiation It is extremely unlikely that increasing the air-supply, which now amounts to from six to ten or more times the cubic content of the car each hour, and must maintain considerable motion of the atmosphere, would and in any other way than by making overheating more difficult to bring about

"Overheating is the paramount evil It is the thing to be chiefly guarded against in the attempt to maintain comfort and good hygiene It is not feasible to cool the naturally overheated air in summer, or to dry it when excessively humid Fan *motors* and *open windows* are the available means by which the difficulties arising in hot weather may be most readily overcome. Carry away the body heat as rapidly as possible by a strong current of air.

"Though the avoidance of overheating in winter would seem to be an easy thing, its accurate control to meet the rapidly changing conditions under which cars may be operated is a matter of great difficulty. Experience has shown that it is necessary to have in sleeping-cars at least twice as much radiating surface as is demanded in common practice for heating the same space in houses, this in order to warm the large volume of air received and discharged so that it will maintain comfort to inactive passengers. To decrease this surface would be to fail to maintain a sufficiently high temperature on occasion

"A system is needed capable of being quickly and effectively controlled to meet rapidly changing conditions Such a system is now being experimented with in which there are multiple units of radiating surface, each with a separate control The results so far indicate that from this a more uniformly comfortable condition can be maintained."

Notes for Inventors

Running a Typewriter With a Perforated Roll.—The problem of manifolding typewritten letters has given inventors no little concern It frequently happens that thousands of letters, all of them alike, are sent through the mails, letters which are in reality circulars in epistolary form, each of which must appear as if it were intended only for the particular recipient into whose hand it falls The market is now almost overcrowded with duplicating machines of various kinds, which imitate, with more or less success, typewritten work One of the most ingenious solutions is the application to the typewriter of the perforated paper roll, which has made the automatic piano player possible. As might be expected, the inventor who has done this, Mr John McTammany, has been identified with the automatic piano player ever since its inception In fact, he has good reason to regard himself as a pioneer inventor of the automatic piano player Mr. McTammany has invented a machine which is to be used

in connection with the ordinary typewriter, and which may be best described as the mechanical equivalent of a pair of hands, capable of turning out ten thousand letters a day. Each letter is an original. As in the automatic piano player, a perforated paper sheet is used. This sheet, whose perforations correspond with certain letters on the typewriter keys, however, does not cause a series of pneumatics to operate, in order to depress the keys of the typewriter, but controls a series of star wheels which actuate the keys. The paper strip is positively fed. By abandoning the pneumatic system of the piano player and yet retaining the perforated roll, the inventor has succeeded in producing a machine which is remarkably compact.

Appreciation of Invention.—It is interesting to note the importance ascribed to inventors and invention in practically all discussions of the developments of business. In a recent article in a popular magazine along the line of business aids and occupying only four short columns, we find reference in three of the columns to three separate inventions, two of which were made by *attaches* of the same business establishment, which is described as encouraging and assisting originality in inventions that can be patented. In explaining his advancement, one of the successful men in the big establishment is quoted as saying that he began making inventions or improving some inventions made by others, and that he was then engaged in the development of another invention.

A Mechanical Violin.—An instrument in the general form of a piano, but seeking to secure the effect of a violin, is sought in a patent, No. 996,614, to Andrew M. Carlson of St. Paul, Minn. He provides in connection with a stringed instrument like a violin two bows near each other upon the same string. These bows are reciprocated in contact with the string slowly at the same speed in one direction and for a part of the stroke simultaneously and are given a more rapid return movement. During the slow movement in contact with the string, the bows are applied to the string partly one at a time and partly both at the same time, so that each bow will continue the note the previous bow is playing before the previous bow leaves the string to make its quick return stroke. A keyboard is provided for pressing mechanical fingers against the strings by power and this keyboard controls the power so it is applied to the right fingers and at the right time.

An Advertising Device.—In a patent, No. 996,929, to Charles W. Saalburg of New York as assignee of Hans Kempinski of Berlin, Germany, is shown an exhibiting device for use in show windows and similar places, including a tank and a bottle above the tank and tilted to discharge liquid into the tank. Liquid is supplied to the bottle by a tube extending upwardly from the tank and through which the water from the tank is forced by a pump. The tube enters the neck of the bottle and the tube is bent between the tank and bottle to conform to the trajectory formed by the liquid pouring from the bottle into the tank so the tube will be within and concealed by the stream of liquid falling from the bottle.

Six Patents to One Inventor.—William D. Forsyth of Youngstown, Ohio, recently obtained on the same day six patents numbered from Nos. 996,620 to 996,634 inclusive. Two of these patents are for metallic railway ties, one for a brake beam, one for a rail joint, and another for a reinforced concrete cross tie, and one for a truck side frame for cars, the latter being assigned to A. M. Neeper of Pittsburg, Pa. It will be noticed that all of the patents relate to the rolling stock or the roadbed of a railway.

A Combined Flying Machine and Parachute.—A flying machine whose planes normally assume a comparatively flat form, but which can be distorted by mechanism controlled by the aviator into the form of a parachute, is presented in a patent, No. 997,122, to Otto A. Fenn of New York.

A Novel Ice-machine.—A patent, No. 993,771, has been issued to Joseph B. Gallagher, of Glen Ridge, N. J., assignor to a New Jersey corporation, for an apparatus for making plate ice including a tank and a vertically arranged freezing plate, combined with a band saw and operating means for the band saw and means for feeding the band saw upwardly in order that it may separate the cake of ice from the freezing plate.

A Guard for Stick Pins.—A stick pin fastening forms the subject of a patent, No. 996,298, to Adinius R. Sunde, of Antonito, Colo., its novel feature being a retaining prong at the back of the head of the pin and spaced away from the head so that, when inserting the pin, the head can be turned slightly to throw the prong away from a neck tie and when the pin is inserted, the head can be partially rotated to force the prong horizontally into the tie.

A New Hydraulic Ram.—An improved hydraulic ram is presented in a patent, No. 996,056, the invention of Edward R. Brodton of Mobile, Alabama. In this patent a water wheel is placed in the casing of the ram and the waste valve of the ram is operated by the water wheel to closed position, the normal tendency of the valve being toward open position.

A Patent to Edison.—Thos. A. Edison has obtained a patent, No. 996,070, for a rotary kiln for cement. The kiln comprises a long tube which is rotated and has a combustion portion at one end. At its other or upper end the tube is of a greater diameter and is divided into a number of passages.

Patents Assigned to Large Companies.—Nothing better illustrates the high estimate in which patents are held by the business public than the attitude toward them of large business corporations, such, for instance, as the General Electric Company, the Westinghouse Co. and the United Shoe Machinery Co. It appears from the list of patents issued June 27th, 1911, that on that day alone four patents were issued to the United Shoe Machinery Co., as assignee, while on the same day more than thirty patents were issued to the General Electric Co., as the assignee of various inventors including among the number such distinguished inventors and scientists as Elihu Thomson and Chas. P. Steinmetz.

A Portable Bathtub.—In traveling in remote sections bathing facilities are not always available. Warren C. Callahan of Louisville Ky., provides for this in a patent, No. 996,453, by a portable bathing apparatus in which a hoop made of a number of flexibly connected sections so it can be easily collapsed by swinging the sections face to face for convenience in carrying, is set edgewise and a water proof cloth is placed over the hoop and depressed within the hoop so the interior of the hoop forms a tub to hold the water while bathing and the edges of the sheet can after the bath, be brought together forming a water bag to carry the water to a disposal point.

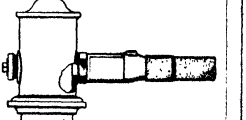
New Wireless Patents.—A number of patents, Nos. 996,088 to 996,092 inclusive, have issued to Maurice Bernays Johnson of San Antonio, Texas, for inventions relating to wireless telegraphy and telephony. One of these patents, No. 996,089, is for a combined wire and wireless telephone system, and another, No. 996,089, is for a combined wire and wireless telegraph system, the former including a wire line at the central station and wireless instruments also at the central station and arranged for connection with the wire line; and wireless communication is established between a transmitter at one end of a space and a receiver and transmitter at the other end of the space, the latter receiver operating its transmitter, switches being provided for connecting the wire line with the wireless instruments and for connecting the wireless instruments with the central operator.

RECENTLY PATENTED INVENTIONS.

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Electrical Devices.

ELECTRICALLY CONTROLLED CLOCK AND TIME INTERVAL TRANSMITTER.—S. I. AIKEN, Fort Mills, Corregidor, P. I. This invention is particularly applicable to time interval signaling, such as time interval apparatus for artillery fire control, or for other analogous uses employing instruments in which absolute chronometrical accuracy, irrespective of the size, or the weight of, or the load imposed upon the controlled mechanisms, is essential.



Of General Interest.

COMPOUND FOR TREATING STEEL.—HARRY M. LEE and FRANK G. BOOTH, New London, Conn. It has been found that by using the solution of this invention as a hardening solution, steels can be hardened to the same degree without the necessity of previously heating the steel to an excessive amount, as has been found in the case of certain types of steels when using other hardening solutions. This solution may be also used in drawing the temper of steel, and in such a case, it is heated to the desired degree and the steel placed therein until the temper has been drawn the desired amount. Since the patent was issued this process has been tried out in large machine shops throughout the country and it has proven highly successful. The patent has been assigned to the Steel Tempering Process Company, 37 Pine Street, New York, N. Y.

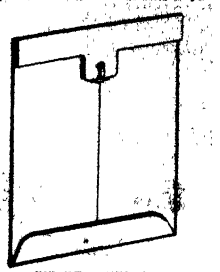
ARTIFICIAL RAWHIDE LEG.—W. H. VANORMAN, Auburn, N. Y. The purpose of this invention is to provide an improved ankle joint. It consists in pivoting the leg portion on an axis longitudinal to the foot and on an axis transverse to the foot with the axes intersecting, and with the bearings for the transverse axis confined together with means for limiting the movement of the leg portion on the transverse axis.

PROCESS FOR STRENGTHENING CELLULOSE.—X. ESCHALIER, Rue des Fleurs, Villeurbanne, Rhone, France. The invention relates to a process of strengthening cellulose bodies, more particularly the depolymerised cellulose bodies in various stages of hydration, produced from solutions in the different solvents. The strengthening according to this process, is in the nature of a polymerisation or a condensation, its effect being very appreciable in the dry State and especially so in the wet.

HOSE COUPLING.—HIRAM W. PETTINGILL, 510 West 58th Street, Seattle, Wash. This invention is an improvement in hose and pipe connections and has for an object to provide a construction in which one of the coupling members will be provided with a packing arranged to be actuated by the pressure of the

HOSE COUPLING.

fluid within the coupled pipes in such manner as to render the pipe joint perfectly tight. It may be utilized in coupling air, water or other fluid bearing pipes and is such as to permit the convenient connection and disconnection of the pipes whether it be applied in connection with a hydrant, as shown in the engraving or in coupling two pipes or hose.



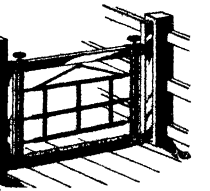
CLEANING PAPER AND PROCESS OF PREPARING THE SAME.—J. R. SMITH, Moline, Ill. This invention is an improvement in a process of treating paper, and the object is to provide a process of this character specified for producing a paper especially adapted for dry cleaning and polishing glass, or the like, without the use of extraneous matter such as soap or cleaning powders.

MOLD FOR CONCRETE STRUCTURES.—J. S. LINTON, Chicago, Ill. The improvement provides a mold or form for making concrete structures, such as walls, columns, beams, etc., and arranged to securely hold the mold parts in position, to allow of raising the mold as the building of the structure progresses, and to temporarily support the concrete material to be used in the formation of the structure.

BAG HOLDER.—P. C. MCCASKILLEN, Walla Walla, Wash. The invention relates to holders for paper bags or similar articles, and has reference more particularly to a device of this class which comprises a frame having both a socket adapted to receive and to hold a plurality of bags, a hook, and a spreader member for releasably holding the bags against the back.

NON-SIFTING ENVELOP.

BUTTON, 216 So. West Temple Street, Salt Lake City, Utah. The object here is to provide means in connection with the envelop for closing the mouth thereof in such manner as to prevent the escape of contaminated or pul-



NON-SIFTING ENVELOP.

verulent substances at the end of the flap, where in the ordinary form of envelop there is an opening between the sealing flap and the back of the envelop. It is designed more especially for carrying merchandise. The envelop illustrated herewith has a sealing flap whose inner portion is a double ply, while its outer is a single ply, and the flap folds by folding the single ply onto the double and then folding the single and the double ply onto the envelop.

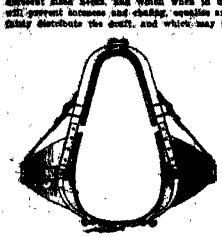
DETONATOR.—R. A. MOORE, Portsmouth, Ohio. In the patent the invention has reference to an improvement in detonators, and the object is to provide means on the end of a cane which can be operated by bringing the cane down upon the ground forcibly, whereby an explosive tape will be fed and exploded.

PLUG STOP.—J. ARMSTRONG, Alvo, Neb. The invention in this instance has for an object to provide a fine stop for securing a fine cap to a fine hole, to prevent dust, smoke, or soot from passing through the fine hole into a room. For this purpose use is made of pivotally connected bars having lateral flanges thereon and adapted to be removably engaged by a holding screw connected with a fine cap.

GATE.—EDWIN COWELL, 969 Atlantic Avenue, Brooklyn, New York, N. Y. This invention provides a gate for stopping runaways on bridges, roadways, and the like without injuring the runaway in the act of stopping the same. For this purpose, use is made of a frame preferably adapted to swing on a post and having an extensible baffle mounted

GATE.

thereon, adjusting rollers being connected with the baffle to normally adjust the same after the baffle has been extended, and the lower side of the frame being preferably padded to ease the force of impact of the runaway against the gate. The device is shown in the perspective illustration in operative position. Precedent authorities on veterinary matters have indorsed its practicability, among them Dr. William Sheppard, a member of the Royal College of Veterinary Surgeons, London.



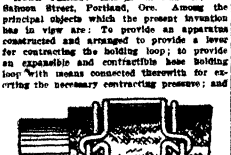
Hardware and Tools.

EARTH BORING AUGER CUTTER HEAD.—F. A. BOUCHET, Merced, Cal. The head has a cutting blade shaped and arranged to form a small centering bore in advance of the main bore. The invention also provides in connection with a cutting blade adapted to form the main bore, a second blade whereby the cuttings from the main blade are broken into smaller particles for the freer delivery from the bored hole; and provides means for dividing and guiding the washing water delivered to the bottom of the bored hole between the blades to elevate the cuttings from the bottom of the bored hole.

PLUGS, WEDGES, ETC.—O. SAMUELSON, Ishpeming, Mich. In the [illegible] of the type comprising a [illegible] and [illegible] [illegible] [illegible]

...ers are forced to the rear to retain the elevator in closed position by a resilient compression spring, in this manner producing a strong and compact hinge structure.

COMBINED HAMES AND COLLAR.—ERNEST SIEBER, Wren, Neb. Mr. Sieber's invention provides a uniform combined collar and hames whereby to dispense with the usual collar and hames, which may be adjusted for different sized teams, and which when in use will prevent sweeney and chafing, equalize and fairly distribute the draft, and which may be



COMBINED HAMES AND COLLAR.

easily placed and removed. The illustration shows the improvement in the position it will occupy when in use, and to remove it, it is only necessary to release the free end of a strap from a buckle. This free end may be now withdrawn from a loop and a ring, when the improvement may be moved from the beast's neck. No injurious strain is brought to bear in any part, the draft being equalized.

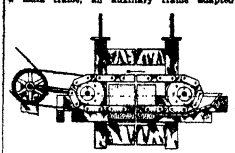
SPRAYING NOZZLE.—G. L. GLASER, New York, N. Y. This nozzle is for use in the uniform and economical distribution of water in the form of light or heavy sprays for irrigation, or for spraying water, insecticides, and other liquids for agricultural and horticultural purposes, also for the equal and economical distribution of water and other liquids for fire extinguishment, and for other purposes where the spray may be advantageously used or applied.

HOSE CLAMP.—HAROLD R. FRANCIS, 474 Salmon Street, Portland, Ore. Among the principal objects which the present invention has in view are: To provide an apparatus constructed and arranged to provide a lever for contracting the holding loop; to provide an expansible and contractible hose holding loop with means connected therewith for exerting the necessary contracting pressure; and

HOSE CLAMP.

to provide means for contracting the clamp and automatically locking the same in contracted position. The engraving shows a side view of a clamp constructed and arranged in accordance with the invention, shown in connection with a pipe hose section, and in locked relation thereto.

CLAMPING DEVICE.—DAVID D. THOMPSON, care of Faber Bros., Fort Pierce, Fla. This invention is illustrated herewith and shows the device in the act of holding a door in an upright position. It relates more



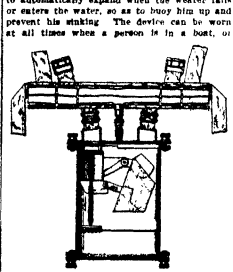
CLAMPING DEVICE.

particularly to devices which are adapted to be used for holding objects, such as doors, blinds, or the like, in a vertical position so that their edges may be planed or fitted with hinges, and comprising jaw members adapted to be moved into engagement with the sides of an object to hold the latter in position. The device in use enables the operator to have both hands free for planing or performing other work on the object so secured.

LOCK.—E. HAMMOND, New York, N. Y. The invention has for its object the provision of a lock which will be durable in construction, strong, efficient, and will permit parts subject to accidental breakage or portion of the lock to be removed, or both easily with the use of a key, to permit the lock to be operated by either side of the door, and which is adapted for differently swinging doors, by having the face plate beveled and removable, and the openings therein located symmetrically.

Machines and Mechanical Devices.

STONE SAWING MACHINE.—HENRY Q. MACKINO, Albuquerque, New Mex. This invention relates to sawing stone and the machine is shown in sectional side view in the illustration. The object is to provide a device for sawing stone, such as marble and the like. For this purpose use is made of a main frame, an auxiliary frame adapted



STONE SAWING MACHINE.

to move vertically, and mounted on the main frame, an auxiliary frame adapted to move horizontally and mounted on the first auxiliary frame, means for moving the vertical frame, means for moving the horizontal frame, rollers on the horizontal frame, and a chain of saws mounted to turn on the rollers, and adapted to saw stone

PACKAGING MACHINE.—M. F ANDERSON, New York, N. Y In this instance the object of the invention is to provide a new and improved packaging machine, more especially designed for packaging rolls of oilcloth, wall paper and the like, in a very simple manner, in compact form and in a comparatively short time, each package containing a number of rolls.

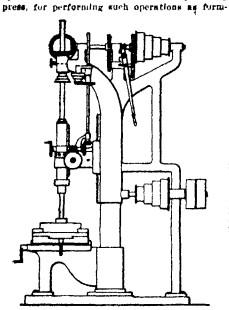
AUTOMATIC LIFE PRESERVER.—EDWARD W. MILLER, Merrick, N Y. The invention pictured in the accompanying engraving relates to an automatic life preserver of a type adapted to automatically expand when the wearer falls or enters the water, so as to buoy him up and prevent his sinking. The device can be worn at all times when a person is in a boat, or

AUTOMATIC LIFE PRESERVERS.

in danger of falling into the water. It is out of sight and unobtrusive when not in actual use, and will immediately expand when the wearer goes into the water, so as to form a buoyant support which will prevent him from sinking, by means of a gas generated on entering the water, which is collected in a substantially fluid-tight envelope

CAMERA EXPOSURE INDICATOR.—C. G IVAS, Norwalk, Conn. This invention provides an attachment to the camera whereby an indicator will denote that a film has been exposed when the shutter is operated. Use is made of an indicator for automatically indicating an exposure when the shutter lever is operated and a connection between the indicator and the film winding mechanism of the camera whereby the indicator is returned to normal position when the exposed film is wound on the winding mechanism.

ELEVATOR.—R. E. SHOWDEN, Snowden, N. C. Pivoted buckets carried by belt members, are provided by this invention, the buckets being free to swing through the belt members and there being means to move the buckets relatively to the belt members. Another object is to provide wheels, having spokes with seats for engaging and directing the belt members. Another is to provide the spokes with members for engaging the buckets and holding them in position relatively to the belt members.



MEANS FOR PRIMING CENTRIFUGAL PUMPS.—L. DESMARAIS, 10 Rue du Banquier, Paris, France. The priming of a centrifugal pump by using the air suction of one or several cylinders of the motor serving to drive the pump, is effected in this invention. The invention applies to any pump-installation, fixed or movable, operated by a motor whatever be its system, steam, compressed air or other, provided that one of the elements of any kind of the motor normally taking part in its working, can be utilized momentarily as suction pump for the priming of the operated pump which being a centrifugal pump, can only suck when it is primed.

DEVICE FOR CARVING AND GAINING.—R. G GUPTILL, Ravia, Okla. The object here is to provide means by which the carving or gaining can be done by machinery without necessitating the use of saw, hammer, chisel or bit and brace A further object of the invention consists in the provision of the device by which stair strips may be gained and which will permit the movement of the stair strip in any direction thereby facilitating the operation

SUGAR WASHING MACHINE.—A. PLESCHER and F. KAMPAN, Las Animas, Col. An object of this invention is to provide a device which will automatically wash a charge of sugar, and when sufficient water has been supplied will shut off the supply. A further object is to provide a reciprocating washing device, the movement of which is accomplished by means of the water, which is used in the sprinkling operation

SAFETY SPRING BARREL.—R L. MARSHALL, Elisabethtown, Ky. An object here is to provide a spring barrel for a watch, disposed upon a solid arbor which extends through the entire length of the barrel, thereby insuring stability A further object is to provide a device in which the size of the jewel holes are reduced, thereby lessening friction, without sacrificing stability

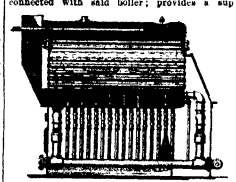
RECIPROCATING AND ROTARY PRESS.—JAMES D. MCCLELLAND, Jr., 40 West 6th Street, Mount Vernon, N Y This invention relates to a machine drill, which can be used either as a drill press for performing drilling operations on the work or as a reciprocating press, for performing such operations as form-

RECIPROCATING AND ROTARY PRESS.

ing mortise and tenon joints, key-seating, face planing, or the like A further object is to provide a machine tool which can be readily changed so as to operate either as a drill press or a reciprocating press, by connecting one or the other portion thereof in driving relation with the main drive The accompanying illustration shows the press in a side view

REGISTERING DEVICE FOR TYPE WRITERS.—H. HARMON Kalispell, Mont The invention is an improvement in registering devices for typewriters, and the object is the provision of a simple, compact, and accurate registering device for attachment to any approved form of typewriter, which will correctly register the number of words written, and which may be easily attached and detached

FLYING MACHINE.—A. H FRISBEL, Baltimore, Md One of the objects in this case is an improved construction of flying machine embodying extensible controlling devices in the nature of slides or curtains which may be opened or stretched at the will of the aeronaut for the purpose of steering to the right or left, or for overcoming the momentum of the apparatus



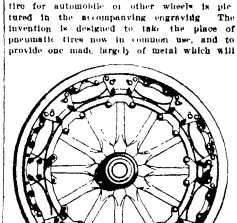
APPARATUS FOR CONDENSING FIBROUS MATERIALS PREPARATORY TO SPINNING.—B BONIE, Werdau, Germany The invention has for its object a roving machine especially designed for treating tow waste and other difficult materials, comprising a film divider and condenser, and characterized by the provision of special means for preventing the films from becoming wound around the edges of the dividing bands or adhering to the same.

Prime Movers and Their Accessories.

INDICATOR FOR SPARK PLUGS.—A. R LAMBERSON, Albany, N Y. In this invention the improvement relates to indicators for spark plugs, the more particular purpose being to provide an indicator having generally the form of a testing tube into which the operator may look in order to ascertain the electrical condition of a spark plug to which the indicator is applied

ROTARY ENGINE.—J. M. FOY, Palatka, Fla. The object of this inventor is to provide an internal combustion, rotary engine which is compact in form, and can be exactly governed, in which the exploded charges are thoroughly scavenged from the cylinders, in which the exhaust gases are to a large extent carried off from the vicinity of the engine, and by means of which any desired number of explosive cylinders can be combined in one prime mover

STEAM BOILER.—NICHOLAS A UHEN, Jr care of Arlington Hotel, Seattle, Wash The invention illustrated here with provides for a boiler a supporting structure formed of water circulating tubes connected with the boiler drum; provides for a boiler of the drum type a fire box, the side and head walls of which are formed in part by water circulating tubes connected with said boiler; provides a sup



STEAM BOILER.

porting structure for the drum boiler so as to avoid lateral extension of the fire box, provides a water circulating system embodying circulating manifolds, provides a connecting pipe between said manifolds to balance water supply therein, and provides a supporting structure for the drum boiler constructed from tubes having screw threaded connections by the manipulation of which the horizontal arrangement of the boiler may be varied

Pertaining to Vehicles.

AUTOMOBILE TORPEDO.—A E JONES, Flume, Austria Hungary The object here is a percussion mechanism or pistol for automobile torpedoes The invention aims more particularly at permitting of the release of the striker no matter at what angle the torpedo strikes its mark, while at the same time avoiding any incorrect operation and the cocking of the striker before and during firing and so long as the torpedo is in proximity to the vessel from which it is launched

FLEXIBLE METALLIC TIRE.—WILLIAM C NICHOLSON, Crown Point, Ind A flexible tire for automobile or other wheels is pictured in the accompanying engraving The invention is designed to take the place of pneumatic tires now in common use, and to provide one made largely of metal which will

FLEXIBLE METALLIC TIRE.

have resiliency and durability, but not be subject to the annoyance of puncture and other inconveniences arising from use of pneumatic tires The tire has sections, each being movable against springs so that as the wheel is rotated, the load comes successively upon the separate sections which give slightly, in the manner of the pneumatic tire.

Railways and Their Accessories.

RAIL JOINT.—E. J DAVIS P O Box 110, Altheimer, Ark This invention is an improvement in rail joints and has for an object to provide a construction whereby to support the rails at the joints as thoroughly and efficiently as they are supported at other points with a special view to overcome the difficulties resulting from low joints incident to the ordinary rail joint now in common use.

Designs.

DESIGN FOR A PENCIL DISPLAY STAND.—W H DALTON, West Hoboken, N J In this ornamental design for a pencil stand, the stand comprises a flat base of curved outline on which are placed the four perforated uprights that hold the pencils A center piece culminating on a point caps the stand and producing an attractive design.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions as in many cases they have to be referred to experts. The full name and address should be given on every letter. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12501) F. M. E asks. Is it worth while for some of our aviators to watch for an opportunity and rise in the wake of a rain cloud and see the rainbow a complete circle? It would certainly be a beautiful spectacle and will be seen by very few. A Whether one would think it worth while to rise in the wake of a rain cloud on the chance of seeing a complete rainbow, we cannot say. It would be a unique experience, if it should be successfully accomplished.

(12502) J. W. C asks. 1. A cubic foot of air in a globe or vessel that weighs, say 2 pounds, would require a certain weight to sink it in water. Now if it is compressed to 64 cubic inches, and the container is same weight, would its buoyancy be the same, or would more or less weight be required to sink it in water to same depth? A. A cubic foot of air at ordinary density weighs about an ounce and a quarter. If it is in a globe which weighs two pounds the whole will weigh the sum of two pounds. If the globe has a volume of one cubic foot, it will displace a cubic foot of water, which weighs if fresh about 62½ pounds and it will be buoyed up by a force of about 60 pounds 6¾ ounces, the difference of the two weights. Now, if the air be compressed to 64 cubic inches, it and its container will weigh the same as before, but will be buoyed up by the weight of 64 cubic inches of water, which you can calculate from the weight of a cubic foot as given above. It will find that the globe will just float in fresh water, the buoyant force being only a very few ounces. 2. What would be the pressure per square inch if a cubic foot of air is compressed to 64 cubic inches? A. If a cubic foot of air is compressed to 64 cubic inches, the pressure at the same temperature will be twenty-seven times the normal pressure, which is 405 pounds per square inch. 3. Have you any books or papers that would be of assistance to a novice in building small rowboats and motorboats? If so, please give me price of same, or tell me where I can get such books. A. We can supply the following books on boat building: "Practical Boat Building for Amateurs," by Nelson, $1; "Canoe and Boat Building for Amateurs," by Stephens, $2; "Nine Motor Boats and How to Build Them," $1; "How to Build a Motor Launch from Plans," by Davis, $1.50; "How to Build a Motor Launch," by Mower, $1. Upon receipt of the prices quoted above, we will forward these books postpaid to your address.

(12503) G. K asks. My friend's boy, a youth of 15 years, came to me and asked me if him made into powder form could be electrified, either with positive or negative electricity. Further, he wished to know what the result would be if both powders were blown through a pipe, one separate at the point of contact. A. Powdered iron can be electrified if it is insulated, and if it were blown from a pipe while charged with either positive or negative electricity, the particles of iron would repel each other and fly apart in all directions. If there were two iron powders, one electrified positively and the other negatively of equal quantity, upon mixing the two powders they would be attracted each other and there would be no charge of electricity left since iron is a conductor of electricity, and can retain it only when it is insulated. We hope that this explains what your young friend wished to know. It would be profitable for such a young man to have the SCIENTIFIC AMERICAN for himself. We hope he may become a subscriber to it.

(12504) A. C. M asks. Will you please be so kind as to give me a formula in your queries column for making a nickel plating solution for electroplating? A. For a small bath for nickel plating dissolve 12 to 16 ounces of the double sulphate of nickel and ammonium, per gallon of water in a stone jar which is perfectly clean. Add water till the solution is of a density of 1.04 to 1.06, or from 6.5 deg. B to 7 deg. B. For large baths a very different method is taken to shorten the time. You will find full instructions in Langbein's "Electro-Deposition of Metals," $4, or in Watt's "Electro-plating," $4.50. A very good small book of very practical instructions is Van Hornes "Modern Electroplating," $1. We shall be pleased to supply any of our readers with these books upon receipt of price.

(12505) W. S. K asks. Can you furnish us the address of a concern where I can buy a microscope? It is used in enlarging of pictures etc. I have never seen one and can only give you an idea of it. It is made of glass. A. We do not know any instrument which is kept for sale to be used in enlarging pictures. This is usually done by dividing the picture into squares, and the paper upon which it is to be copied into the same number of squares. Then, as you will see, any portion of the picture will be drawn to fill the square on the copy which corresponds to the square which it fills in the original picture. A plate of glass ruled in squares and over the picture would be very convenient but you can rule fine pencil marks over a picture and afterward erase them, or you can make a light frame and draw a thread across it to form the squares. Other ways will suggest themselves to you for making the square, cheaper than buying a frame.

(12506) D. S asks: 1. Supposing that a retort or any other receptacle was filled with pure air (with of course provision for its expansion) and heat was applied to the outside of the retort sufficient to raise the temperature of the air in the retort to say 1,000 deg. or 1,200 deg., would that air be fit to breathe after it was cooled to the ordinary atmospheric temperature? A. If pure air containing only oxygen, nitrogen and the other gases which are found in minute quantities in pure air should be inclosed in a retort and heated to 1,500 deg. Fahr., and again cooled, no change would take place in the air. It would be the same as before the heating in every respect. It could be breathed with entire safety. 2. About what proportion of the oxygen would remain in that air, or would nearly all of the oxygen be burned out of it, being as it were entirely isolated from the outside fire? A. The oxygen of the air could not burn with any other substance in pure air in the retort. To cause the oxygen to combine with the nitrogen a temperature very much above 1,500 deg. Fahr. is required. None of the oxygen would be burned at that temperature.

(12507) W. H. P. asks. 1. In the practice of wireless telegraphy does the circuit run thru the air, or do they use the air as one wire and the ground for the other? A. A wireless telegraph message is not sent by means of an electric current flowing over a circuit as ordinary telegraph messages are sent. It is sent by means of waves which are sent off into space by the energy of the transmitting apparatus. In the present method of signaling the waves remain fixed to the surface of the earth, and spread in this manner outward in all directions from the aerial wire. Over water they flow with little retardation. Over the earth they follow the surface, up and down as may be, and are impeded so that they die out sooner and do not reach as far as over water. They do not act at all as if they were following a wire. 2. Is there a way in which the receiving instrument of wireless telegraphy can be arranged so that it will be able to receive from a fixed distance from a mile of the transmitting instrument before it can receive a message, and can receive a message all the time within the radius of this distance? A. The receiving instrument can receive audible any signal which is powerful enough to affect it. It is a matter of the sensitiveness of the detector. The receiver must be tuned to the same wave length as the transmitter and the detector can then pick out the signals that it is adapted. It is not so much the distance from which the signals have come as the energy of the signals and the delicacy of the receiving apparatus.

(12508) W. A. W asks. 1. How is it possible when listening to a phonograph to hear more than one sound at the same time, although only one needle and one diaphragm, which I assume can only vibrate at one rate of speed, are responsible for the sounds? As an illustration, one hears a vocal solo and accompaniment at the same time. A. Your question about the reproduction of music by the talking machine would be unanswerable if it were true that a diaphragm could only vibrate at one rate of speed. The diaphragm of a piano, the sounding board, vibrates for all the sounds of all the notes and their harmonics. The same is true of the diaphragm of a violin, which is the wood of the back and belly. A plane piece of elastic material, such as in the diaphragm of the recorder and reproducer of a talking machine, has the ability, to vibrate in an indefinite number of modes at one and the same time, and the tracing by the needle point is a complicated one which represents all which you hear coming from the machine. 2. Why is it that the tea kettle full of boiling water may be taken from the fire, and sustained from below by the bare hand for several seconds, the bottom of the kettle feeling nearly ice cold to the touch? A. The ability to carry a kettle of boiling water upon the bare hand depends upon several facts. The kettle is no hotter than the water it contains. Any layer of soot which may be on the bottom of the kettle is a non-conductor of heat and protects the hand from the heat of the kettle. The moisture of the hand must first be evaporated before the hand will feel the heat of the kettle. The evaporation of the moisture of the hand causes the hand to feel cool, or as you state it, to feel that the kettle is cold. When all this is over it is time to set the kettle down, for then the metal will burn the hand.

NEW BOOKS, ETC.

THE IGNITION HAND-BOOK. By H. R. Van Deventer, E. E. Price, 50 cents.

Defective ignition is a great trouble maker. The first part of this tract is devoted to the various ignition systems and equipment, and the methods of installing and operating them. The features of the high and low tension systems, popularly known as the jump-spark and the make and break, are explained by text and illustration, and their respective adaptabilities, excellencies, and drawbacks are catalogued. The latter part of the treatise is given over to a particular type of magneto manufactured by a Southern firm.

THE STEEL WORKERS. By John A. Fitch. New York. Charities Publication Committee, 1910. 8vo., 240 pp.; illustrated. Price, postpaid, $1.71.

"The Steel Workers" gives us a series of vivid glimpses into the changing, roaring, seething inferno of the mill—glimpses that, like the impressions on a running cinematograph film, merge into one faithful picture of men eternally in action at hammer and furnace, at charging machine, stripper, and rolls. Sparks and vapors and molten iron create a background spectacular in the extreme, but the men who toil before this scenic display for twelve hours each day are conscious only of a stern, prosaic duty to be done in the face of ever-present danger, with a weary body at the day's end. "Homestead," Margaret Byington's contribution to the Pittsburgh Survey, took up the family side of the employee's existence. "The Steel Workers" shows us the man in relation to his work. Since the great strike of 1892, which resulted in victory for the employer, the subjugation of the employee has been complete, and men have been discharged for calling meetings to discuss the issues which Mr. Fitch handles in the present volume. As one old resident said, "If you want to talk in Homestead, you must talk to yourself." So Mr. Fitch takes up the cause of the man whose life is molded and fixed by the inexorable will of the steel kings, and leaves to others the interpretation of the steel industry from its administrative, commercial and technical sides.

METAL WORK AND ETCHING. By John D. Adams. Chicago: Popular Mechanics Company, 1911. 12mo.; 88 pp., illustrated. Price, 25 cents.

This is a handbook giving a list of the simple tools and materials, with concise directions as to their use in the fabrication of such novelties in metal as desk sets, candlesconces, hinges, photograph frames, and jewelry. The designs are in excellent taste, and open up a large field of artistic handiwork to those whose choice falls upon occupations and hobbies of this kind.

HEAT. By J. Gordon Ogden, Ph.D. Chicago: Popular Mechanics Company, 1911. 12mo., 119 pp. Price, 25 cents.

There are doubtless many who will welcome a short, popular exposition of high and low temperatures in their relations to applied mechanics and the phases of the subject which pass under examination are: Heat and its measurement; the production of low temperatures and their effects upon matter, the production of high temperatures and their uses in connection with the rare metals, the laws of expansion and contraction. There are also chapters on energy and fuels, artificial ice, and steam, boilers and engines.

THOUGHTS ON THE BOOK OF REVELATION. By Uriah Smith. Washington: Review & Herald Publishing Association. Price, 25 cents.

The expounder argues that the very name shows this to be a book of revelation and not a manuscript of concealed meanings. He endeavors to follow what is known as the literal system of interpretation, and to explain the figures, symbols, words and phrases in their commonest significance and attempting to show that history has responded to the voice of prophecy.

UNDER THE ROOF OF THE JUNGLE. A Book of Animal Life in the Guiana Wilds. By Charles Livingston Bull. Boston. L. C. Page & Co., 1911. 8vo.; 271 pp.; illustrated. Price, $2 net.

It is indeed an "amazing landscape" which is here unfolded before us in description and illustration, and the *dramatis personae* are no less remarkable and sensational than their background. Still, the Guiana jungles are places where the sensational becomes the commonplace. There are stories of jungle cats that play with rolled up armadillos as a kitten does with a ball; of troops of black spider monkeys, precipitating themselves from tree to tree in their terror-stricken flight from the jaguar of curious and deadly encounters in which birds, beasts and reptiles take part; of strange, loathsome little animals, of birds of ill-omen that follow a tapir calf for days, and of "green dragons" and "crested robbers" that lurk in foliage and prey upon the weak. Whether some of the situations into which the writer brings his animal actors are over drawn or not we can not say, but he has certainly succeeded in making real to his reader some of the glamor, some of the mystery, and some of the horror of the haunts he describes.

LEGAL NOTICES

OVER 66 YEARS' EXPERIENCE

PATENTS

TRADE MARKS
DESIGNS
COPYRIGHTS &C.

INVENTORS are invited to communicate with Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D. C., in regard to securing valid patents, protection for their inventions, Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured.

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our Hand-Book on Patents will be sent free on request.

Ours is the Oldest agency for securing patents; it was established over sixty-five years ago.

Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than ten lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

FOR SALE.

FOR SALE.—Complete set Patent Office Reports for the year 1858 to 1871 inclusive, 14 bound volumes of Official Gazette from 1872 to 1880 inclusive, unbound volumes and odd parts in good condition. Address P. O. Box B, Mamaroneck, N. Y.

HELP WANTED.

SUPERINTENDENT Metal Department of a large manufacturing concern. One who thoroughly understands the making and finishing of articles from sheet metals. No one who is not thoroughly experienced need apply. Address "Superintendent," Box 773, New York.

WANTED.—A first-class American automobile machinist, to take charge and to act as foreman in an up-to-date Garage. Please state experience. Address Youngs & Co., Newburg, N. Y.

PATENTS FOR SALE.

FOR SALE. Patent No. 987 105. Improved valve for combustion engines. Is cheaper to build than poppet valves and is noiseless. Will sell outright or royalty or shop-rights. Address O. Troser, 3080 Tenth Avenue, New York City.

FOR SALE. Canadian Patent No. 131 987. U. S. No. 987 105. Dated March 14, 1911. On a device which will keep trolley on the wire when rounding curves. For particulars write to Frank H. Crane, 850 W. 85th Street, Cleveland, Ohio.

THREE VALUABLE PATENTS FOR SALE, staple goods, hardware line. Articles already marketed. Good profits, owner retiring. Particulars on request address Edward L. Nelson, 29 Warren Street, Providence, R. I.

FOR SALE. U. S. Patent No. 987,247. Automobiles seal. Consists of ring, jack, plug, cap, chain, and pinch bar. Nothing of its type or character on the market. A sure seller. Will sell outright or on royalty. Address F. S. Baird and William Peters, Jackson, Cal.

REAL ESTATE.

IMPROVED FARMS. Large or small, seventy miles from Chicago markets, compare favorably with the very best crops and wheat. Land values increasing. $20 per acre. Write for list. Robert D. Peters Estate, Indiana.

MUST BE SOLD. Modern 8-room house, with corner lot, timber, balance rentals for 60 sales cotton. Two miles to good school, churches and depot. Tinsley Worth double tax price, $3,000. Write or wire R. F. Hall, owner, Anderson, South Carolina.

WANTED.

LOCAL REPRESENTATIVE WANTED. Splendid income assured right man. We want at once a reliable and energetic man to act as our representative after learning our business thoroughly by mail. Previous experience unnecessary. All we require is honesty, ability, ambition and willingness to work. Permanent position with advancement. Splendid opportunity for man of small capital. This is an exceptional opportunity for a man to connect himself with a big growing business. Enquiries and persons independent for life. Write us once for full particulars. Address: The Manufacturers, The National Co-Operative Real Estate Company, L. 276, Marden Building, Washington, D. C.

Michigan Boulevard, Chicago.

CIVIL SERVICE EXAMINATIONS open the way to good Government positions. I can coach you by mail for any U. S. Civil Service examination. Write for free synopsis of examination you want. Write to-day for Booklet 156. Hunt Hopkins, Washington, D. C.

LISTS OF MANUFACTURERS.

COMPLETE LISTS of manufacturers in all lines easily obtained in short time. Catalogue free. Small and special lists compiled to order at various prices. Classified Directory of Inventions, containing 700 headings, for sale cheap. Thomas Register, 96 Fifth Ave., New York.

INQUIRY COLUMN

Inquiry No. 9244. Wanted addresses of parties having Pitchfordine deposits, or sales to ship one.

Inquiry No. 9245. Wanted addresses of firms selling second-hand water turbines.

Inquiry No. 9246. Wanted addresses of parties having corn elevators to offer in any part of the world.

Inquiry No. 9247. Wanted to buy a machine for removing the husks from a cocoanut.

Inquiry No. 9248. Wanted the address of parties to whom cocoanut fiber, either in the husk or after husking, is available as an article.

The Heavens in August

(Continued from page 104.)

the month, when he is farther north.

Venus is likewise evening star, but being farther from the sun than Mercury, and very much brighter, is a conspicuous object. She reaches her greatest brilliancy on the 10th, after which the rapid narrowing of her crescent, as she comes between us and the sun, more than makes up for the increase in her apparent size as she approaches us

At the beginning of the month she sets at 8.40 P. M., and on the 15th a little before 8 P. M. After this she approaches the sun very rapidly, and by the 31st she will be hard to see as she sets about 6.45.

At the beginning of the month she appears as a crescent some 35 seconds in diameter, and 12 seconds in width On the 31st her diameter has increased to 54 seconds, but her crescent is only 4 seconds wide, so that she sends us less light than before.

Mars is in Aries, and rises a little before 11 P. M on the 15th He moves slowly eastward, and increases in brightness and apparent size as the earth overtakes him.

Saturn is close by, but is moving more slowly, so that Mars overtakes him early on the morning of the 17th At this time the two planets are apparently separated by only 21 seconds—about ⅛ the moon's diameter. The moon herself is close by—about four degrees to the southward—and the triple conjunction will be a pretty spectacle in the morning sky

Jupiter is evening star in Virgo, setting about 10 P M. in the middle of the month Uranus is in Sagittarius just past opposition, his position on the 15th being R. A. 19 h 54 1 m, Dec., 21 deg 26 min Neptune is in Gemini, and rises about two hours before the sun

The moon is in her first quarter at 6 P M on the 1st, full at 10 P M on the 9th, in her last quarter at 7 A. M on the 17th, new at 11 P M. on the 23rd, and in the first quarter once more at 11 A M. on the 31st She is nearest us on the 21st, and farthest off on the 5th

As she passes round the skies, she comes into conjunction with Jupiter on the 1st, Uranus on the 8th, Mars and Saturn on the morning of the 17th, Neptune on the 21st, Venus and Mercury on the 25th, and Jupiter again on the 29th

KIESS'S COMET

A comet, visible in an opera-glass and possessing a tail, was discovered by Kiess at the Lick Observatory on July 6th

At that time it was in the southern part of Auriga, and rose about four hours before sunrise

The Original Paper Makers

(Continued from page 105.)

the main business of the nest. In the summer and autumnal months, they go forth by myriads into the neighboring country to collect provisions; and on their return to the common den, after reserving a sufficiency for the nutriment of the young brood, they divide the spoil with great impartiality; part being given to the females, part to the males and part to those workers that have been engaged in extending and fortifying the community. This division is voluntarily made without the slightest symptom of compulsion. Several wasps assemble round each of the returning workers and receive their respective portions. It is curious and interesting to observe their motions upon this occasion. As soon as a wasp that has been filling itself with the juice of fruits, arrives at the nest, it perches upon the top, and upon disgorging a drop of its saccharine fluid, is attended sometimes by two at once, who share the treasure. The first drop being thus distributed, a second and sometimes a third is produced, which falls to the lot of the others.

"Wasps do not as a rule store up honey, but it is found in the cells of some European species as well as in those of America.

"Another principal employment of the workers is enlarging and repairing the nest. They work with great celerity, and though a large number are occupied at the same time, there is not the slightest confusion. Each individual has its portion of work assigned to it, extending from an inch to an inch and a half, and is furnished with a ball of ligneous fiber scraped by its powerful jaws from posts, rails and the like The workers also clean the cells and prepare them to receive another egg, after the first has passed through all the stages of its life and is now a perfect insect working with the rest"

There is good reason for thinking that wasps have sentinels placed at the entrances of their nests, which, if you can seize and destroy, the remainder will not attack you This has been confirmed by the author and many other entomologists. If a nest of wasps be approached without alarming the inhabitants, and all communication be suddenly cut off between those out of the nest and those within it, no provocation will induce the former to defend it for themselves, but if one escapes from within, it comes with a very different temper and appears commissioned to avenge public wrongs In fact, very few incoming bees or wasps will attack the intruder Perhaps it is because the insect who is returning to the nest sees from afar all that is going on about its home, while the one coming from inside the nest is confronted suddenly by an unusual form when it reaches the usual point of exit It becomes alarmed, not only for itself, but for the safety of its colony What follows is only too well known to the student of social insects' When the workers make their rush they are prepared to sacrifice their lives in the execution of their orders

The first cold weather, after the queens have entered their winter quarters, produces an effect upon them similar to that which is produced upon the wood chuck and other animals subject to torpor At first a partial benumbment takes place, but the insect if touched is still capable of moving its organs As the cold increases all the animal functions cease The insect breathes no longer and has no need of a supply of air; its nutritive secretions cease, no more food is required, and it has all the external symptoms of death

Thus we will leave the few survivors of a once great insect empire, perhaps huddled behind the picture molding in our bedroom, insignificant now to be sure, but planning, nevertheless, in their insect minds every cell, every gallery, and every passage which is to be built when the new colonies are founded in the first warm days of April.

1912 Prospects for Automobile Industry

By Hugh Chalmers

WITH a great many of the standard cars for 1912 already announced, and with a new manufacturing season well under way, I have no hesitancy in predicting that 1912 will be a most prosperous year for the automobile industry

I do not say this as a mere matter of form, but because I really believe it Every large manufacturer of motor cars is vitally interested in the prospects for business I know of many men in the industry who, after careful investigation of conditions, have arrived at the same opinion as myself

In my opinion success in the automobile industry depends upon the solution of a manufacturing problem The days of rapid fire manufacturing and selling, of pyrotechnics and hail-fellow-well-met methods are past We all know that water will reach its level. It cannot flow up hill and it is bound to flow down as soon as some of it is drained away

The water has been drained out of the automobile industry

I believe there is a tremendous market both in the United States and abroad for American made automobiles. I consider this market will last not only this year and next year, but for many years to come Yet it is possible in any one season to flood this market. Over-production is the greatest danger to the automobile industry; or, at least, to those manufacturers who do not immediately realize that building and selling automobiles is a manufacturing proposition just like the building and selling of any other commodity.

There is a great market, for instance, for adding machines. Yet it would be

—"And you must take Sanatogen regularly for several weeks"

THIS urgent advice is given by physicians day by day in every civilized land—wherever sufferers from starved nerves and poor digestion seek relief. There is a reason for this. Physicians know that Sanatogen is a substance capable of supplying the real needs of a starved, overwrought nervous system—that it is a scientific combination of albumen and organic phosphorus—a compound eagerly absorbed by the hungry tissues and possessing unique tonic and reconstructive qualities They also know from their own *observation* what Sanatogen has done for others They have watched its revivifying action upon persons whose nervous strength had been undermined by overwork, worry or disease, they have observed how it has infused renewed energy, life and elasticity into starved nerves, how it has regenerated the appetite, digestion, in short, how wonderfully it has helped to make the human machinery fit to perform its functions in the most perfect manner

There are on file with the owners of Sanatogen no less than 15,000 letters from practising physicians praising, endorsing Sanatogen Truly, a magnificent monument to the value of this food-tonic

But no less impressive is the enthusiastic testimony of patients themselves Men and women in the forefront of human endeavor, statesmen, prelates, authors, lawyers, have written about their own signatures of the wonderful benefits received from Sanatogen

We ask you earnestly to get acquainted with Sanatogen Investigate our claims first, if you like, and we are only too glad to have you do so. Ask your doctor about it, and in any case write at once for our book "Our Nerves of Tomorrow" the work of a physician-author, written in an absorbingly interesting style, beautifully illustrated and containing facts and information of vital interest to you This book also contains evidence of the value of Sanatogen which is as remarkable as it is conclusive

Sanatogen is sold in three sizes, $1.00, $1.90, and $3.60

Get it from your druggist, if not obtainable from him, send upon receipt of price

The Bauer Chemical Company, Union Square, New York 515 EVERETT BLDG

Hon. Miles Poundexter

U. S. Senator from Washington writes:

I am sure Sanatogen has benefited me greatly. A few weeks' use of it has produced better digestion, better sleep and a feeling of greater strength."

Hon. John. W. Kern

U. S. Senator from Indiana, writes:

As a restorative and tonic Sanatogen has been of real benefit to me. I feel sure that this preparation is deserving all the praise that has been bestowed on it."

Harrison Fisher

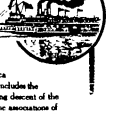
The well-known artist writes:

I have used Sanatogen from the first of the year and find it a wonderful tonic I am recommending it to my overworked friends."

John Burroughs

The distinguished naturalist and author writes:

I am sure I have been greatly benefited by Sanatogen. My sleep is fifty per cent better than it was one year ago, and my mind and strength are much improved.



Solders and Soldering

¶ If you want a complete text book on **Solders** and the art of **Soldering,** giving *practical, working* recipes and formulæ which can be used by metallurgist, the goldsmith, the silversmith, the jeweler, and the metal-worker in general, read the following *Scientific American Supplements:* 1112, 1384, 1481, 1610, 1622, 1434, 1533, price 70 cents by mail. ¶ Order from your newsdealer or from

HOW TO MAKE A 100-MILE WIRELESS TELEGRAPH OUTFIT

In the following *Scientific American Supplements*, the well-known wireless telegraph expert, Mr. A. Frederick Collins, describes clearly and simply, without the aid of mathematics, the construction of a 100-mile wireless telegraph outfit. Complete drawings accompany his descriptions

1605—The design and construction of a 100-mile wireless telegraph set.

1622—The location and erection of a 100-mile wireless telegraph station

1623—The installation and adjustment of a 100-mile wireless telegraph station is fully explained.

1624—The adjustment and tuning of a 100-mile wireless telegraph outfit

1625—The theory and action of a 100-mile wireless telegraph outfit.

1628—The management and operation of ship and shore stations is clearly set forth

¶ These six articles constitute a splendid treatise on the construction, operation and theory of wireless telegraph instruments The complete set will be mailed to any address for 60 cents Single numbers will be mailed for 10 cents ¶ Send for a 1910 Supplement catalogue free to any address ¶ Order from your newsdealer, or from

MODEL NO. 3

The Kullmer Equatorial Star Finder

The new model is now ready for delivery. This is the first star finder that points directly at the stars. Less than a year on the market it is already used by most of the large observatories; it is, however, especially intended for and adapted to the amateur astronomer. The price of the new model is $10, express paid.

Height, 10¼ in. Adjustable to latitude.

Money refunded if not satisfied. Send for circular.

DIVINE WATER MOTOR CO.

ridiculous to think that manufacturers could build two or three hundred thousand adding machines every year and not flood the market

I think some manufacturers of automobiles have not yet come to a full realization of the fact that they can build too many cars. Those manufacturers, I surmise, are apt to find 1912 a very hard season before they are through with it There are some who may find themselves in serious difficulties in the next couple of years unless they plan more conservative operations than they have attempted in the past

Every manufacturer must realize that for every thousand of population there is only a certain percentage of men of enough means to buy motor cars The automobile manufacturer must consider his market The percentage of people of means in every community is almost as exactly as the mortality rates Only trouble can result from trying to go beyond the fact.

In my opinion the future of the automobile industry lies in the thoroughly standardized medium priced cars. The higher priced cars have a much more limited market than the medium priced cars They cannot be built in as large quantities, and yet, quite as elaborate manufacturing facilities are required for their production On the other hand, there are on the market at this time a number of medium priced cars which will give to the average buyer all the service he could purchase at any price For this class the future possibilities seem to me to be practically unlimited

I believe, too, that the market for the American medium priced car will extend to all of the automobile centers of Europe. There can be no question but that the American manufacturer is better equipped to build a good medium priced car than his European competitor

But the medium priced car which is to be a continued success must be well built, well finished and well equipped It must be able to compete with high priced cars, without discredit to its owner To this end all of the leading manufacturers are working

In this matter of greater automobile values one again has purely a manufacturing problem The high-grade, medium priced car of the future, I suppose, is going to be possible only in an economically conducted factory I believe this means eventually that nearly all standard manufacturers will be making most of their parts in their own shops

In the methods of manufacture, too, there have been opportunities for extravagance and waste which, unless eliminated, will create disastrous disproportion between price and value

I warrant that most of the recognized standard manufacturers have been giving the public more value each year for their money, and I believe that most of these standard manufacturers have now reached the point where they are making only a legitimate manufacturing profit, and in some cases are not making nearly as big a percentage as is considered perfectly legitimate in standard lines

I think that those manufacturers who build cars of high dollar for dollar value and at the same time refrain from overproduction, have nothing to fear from the future The automobile has taken a firm place in modern civilization The world cannot do without it now and will not do without it in the future The motor car is no longer a toy or a luxury; it is a necessity There will be a demand for automobiles just as there has always been a demand for horse-drawn vehicles, until something better than the automobile is devised to take its place. With this steady demand I see no reason why a conservative production of good cars at a fair price should not always bring success.

Numerous Gall-stones

THE French surgeon, A. Schachner, removed 14,000 gall-stones from one patient in one operation. Being greatly impressed by the large number, he sent out a questionaire to certain prominent surgeons, asking them to state their experiences as to this point His results are published in the *Gazette des Hôpitaux*; some of the figures are as follows: Mayo-Robson, often found over 500; at one time 1,058; 2,300. Moynihan, more than 3,000; 7,000 in one case. Mayo, 5,000-6,000. Eschner, 6,780. Deaver, 2,252. Dunlop, 2,011. Morgagni, 3,000. Hoffmann, 3,646. Langenbuch, 4,000. Nauhyn, 5,000. Otto, 7,082.

Gall-stones vary in weight from a few grains to about one ounce. When single, they are usually ovoid in shape, but when present in large numbers they are angular in outline Gall-stones are much more common in the gall-bladder than is generally supposed. There is hardly an autopsy on an elderly person that does not show from one to several. As long as they are in the gall-bladder they are quite harmless But when they start to go down the bile duct they are likely to cause serious trouble.

The Current Supplement

FEW of us realise how the science of geography has changed in recent years. A geographer nowadays is a man who studies environments, who examines the forms and qualities of the earth's surface, and who recognizes, defines, and classifies the different kinds of natural units into which it can be divided. His work consists in collecting new information, and in making use of the material thus collected. Mr. A. J. Herbertson, of the University of Oxford, sets all this forth in a highly instructive article in the current SUPPLEMENT, No. 1856.—That light actually exerted a pressure was first experimentally demonstrated by Peter Lebedew and by Professors Nichols and Hull In an article entitled "The Pressure of Light on Gases," Prof. Lebedew presents the results of an experimental application of the theory to comets' tails.—The planimeter is one of the most widely used of the measurement instruments employed by engineers. So few understand the principles on which the planimeter is based or the methods employed to determine if a particular instrument in use is giving correct results, that Mr W L. Durand's article on the subject will undoubtedly be welcomed.—Mr. Frederick C Coleman contributes an article on a wire rope tramway for German East Africa, which does some remarkable work in an inaccessable yet rich region of Africa.—Mr. Donald Murray, one of several inventors who have done their utmost to introduce the page printing telegraph, presents the first instalment of an elaborate treatise on "The Practical Aspects of Printing Telegraphy" in which he thoroughly discusses the type of machinery that must be employed and the commercial possibilities of that machinery.—Mr. S O Mast writes on the effect of light on the movement of the lower organisms. —The practical application of meteorology to aeronautics is considered by W. H. Dines.—Among the articles of minor interest may be mentioned those on the famous star No. 61 Cygni, "A Kerosene Oil Tractor for a Narrow-gage Native State Railway in India," "The Foundation Walls of the Giant Steamship Europa," "A New Registering Steam Meter," and "New Physical Apparatus."

American Phosphate

THE phosphate lands which a year or two ago were withdrawn from entry for settlement by the Federal Government, constitute, it is said, the greatest known phosphate deposit in the world. These lands comprise nearly the whole of Uinta County in Wyoming, and portions of Morgan, Rich and Oache counties in Utah, and of Bear Lake, Bannock, Bingham and Fremont counties in Idaho, making in all about 7,500 square miles of territory which is more or less underlain by phosphate rock. Besides these vast natural deposits, it is pointed out that the gases from the smelters at Butte and Anaconda, which are very injurious to vegetation, may be made to yield sulphuric acid for the manufacture of superphosphate fertilizers.

A Model Hydroplane

ON June 18th, 1911, Mr. Francis Lee Herreshoff and Dr. Carleton Dederer succeeded in making a hydroaeroplane model thirty inches long raise off the water with its own power in a distance of four feet and make a sustained flight for about 350 feet at a height of about 15 to 20 feet in Central Park, New York.

A Thoroughly Sound Timber Bond

Netting 6%

These bonds are secured by First Mortgage upon standing timber, land, mills, railroad and other property conservatively valued at nearly four times the amount of the issue. The stockholders have an actual investment behind the bonds of more than two and a half times the bond issue. Based upon present operations the net earnings will show a large margin over principal and interest requirements. The mortgage provides for a sinking fund sufficient to retire this bond issue from the exhaustion of considerably less than half of the timber security. The bonds mature in equal semi-annual installments from six months to ten years and the margin of security will rapidly increase. We recommend these bonds as a most conservative investment.

Electricity

Turbine-driven Vessel With Electrical Speed Reduction.—Opportunity for comparing the performance of recent improvements in speed reducing gears with generator-motor systems of connection between steam turbines and propellers will be offered in the construction of two sister ship colliers now building for the United States Navy, as we read in the *Electrical World*. The new collier "Neptune" is to be equipped with Melville MacAlpine reducing gears, while the turbines of the new coal-carrier "Jupiter" will drive generators which in turn supply energy for operating the motors on the propeller shafts.

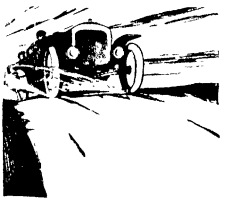
Power Brakes on New York Surface Lines.—The Public Service Commission has been considering the advisability of requiring all the surface railways of Greater New York to equip their cars with power brakes and folding steps. If this is carried out, says the *Electric Railway Journal*, it would mean the equipment of 3,630 cars, distributed among the following companies: Metropolitan Street Railway, 622, Second Avenue Railroad, 250, Brooklyn Rapid Transit, 1,807, Coney Island and Brooklyn Railroad, 459, Long Island Electric Railway, 16, New York City Interborough Company, 40, Richmond and Midland Companies (Staten Island), 20, Union Railway, 416. In 1910, 455 accidents were reported with double-truck cars equipped with hand brakes.

Terrestrial Magnetism.—The first mention of a magnetic pole is made by Girolamo Fracastro in 1538. Fifty-eight years later Livio Sanuto makes mention of two magnetic poles. The scientific development of the theory of terrestrial magnetism may be said to have taken its origin in the hands of William Gilbert (1600), who regarded the earth as a great magnet. This is the same Gilbert who first applied the term "electric forces" to the attraction and repulsion manifested by rubbed amber (Greek "elektron"). Certain variations of the magnetic declination were shown to have a period of twenty-six days by Broun (1861), and the significance of this observation was pointed out in 1887 by Adolf Schmidt, who drew attention to the parallelism between the period of declinations and that of sunspots.

The "Loading" of Telephone Circuits.—In an editorial comment upon the effects of the recent hot weather upon the telephone traffic, the *Electrical World* remarks: The recent hot wave, unprecedented in the records of the Weather Bureau for certain sections of the country, has had a remarkable effect in nearly doubling the normal volume of telephone traffic in some of the Eastern cities and towns. The regular telephone subscribers acted as though they could best keep cool by keeping the telephone switchboards hot. It is said that the modern telephone system has rendered possible the modern many-storied office building, by replacing the messengers that would otherwise overcrowd the elevators, so that the telephone is the reincarnation ghost of the displaced messenger boy. Now it may be said that the modern telephone system has substituted talking for walking in the hot wave intervals of the American summertime.

The History of the Oscillatory Discharge.—It is interesting to note the historical sequence of events leading up to the full understanding of the phenomenon of the oscillatory discharge, which is at the present day of such interest in connection with wireless telegraphy and the design of lightning conductors. The first observation having any bearing on the subject might be said to be that of the astronomer, Felix Savary, who in 1874 observed that the discharge from a Leyden jar would magnetize a needle sometimes in the one direction, sometimes in the opposite. This observation was repeated in 1842 by the great American physicist, Joseph Henry, who rightly attributed the effect to the oscillatory character of the discharge. The theory of the discharge from a condenser was worked out in 1853 and the succeeding years by William Thomson (Lord Kelvin), and Feddersen succeeded in 1858 in actually rendering visible to the eye the alternations in the spark discharge. This was accomplished by means of a rapidly revolving mirror.

Science



The Zodiacal Light.—The zodiacal light, the nature of which is still a mystery, sometimes presents very regular pulsations in intensity and form. In a recent note in the *Comptes Rendus*, Birkeland has stated that these pulsations correspond very closely with the periods found for regular magnetic waves in the polar regions, whence it is suggested that the zodiacal light may have an electrical origin. On the basis of several experiments Birkeland suggests that there may be a ring of luminous matter extending in the plane of the sun's magnetic equator.

White Water.—In a recent pilot chart of the British Meteorological Office many observations of the singular phenomenon called "white water" are collected. It is more frequently seen in the tropical parts of the Indian Ocean than anywhere else, and it impresses some observers as weird, ghastly and awe-inspiring. The ocean has a milky look and the ship seems to be passing through a kind of luminous fog, in which sea and sky appear joined and the sense of distance is lost. The phenomenon is believed to be due to some form of phosphorescence, but a satisfactory explanation of it is yet lacking.

Wonderful Wells of South Dakota.—East of the Missouri River in South Dakota, it is estimated, more than one thousand artesian wells now exist, drawing their water from the supply carried by the underlying sandstone formation, and supposed to come from the Black Hills and the Rocky Mountains. These wells, used mainly for irrigation purposes, are from 500 to 1,000 feet deep, and the pressure of water in the eastern part of the State is sufficient to give a surface flow, except on the highest lands. One well yields 3,292 gallons per minute, and furnishes power for a flour mill by day and for an electric light plant by night. The development of this source of water supply is still going forward.

Meteorological Wireless Telegraphy in Japan.—In the *Journal of the Meteorological Society of Japan* for May 1911, T. Saki writes of the use of wireless telegraphy in the Japanese weather service. The first wireless weather messages were sent for some time in 1906 between the temporarily established naval semaphore on Hachijojima and the Central Meteorological Observatory. The present system went into operation in May, 1910. All vessels passing within range of wireless communication with any coast station are requested to send a cipher report of meteorological observations taken at 6 A M., 2 P M., and 10 P M. to the Central Meteorological Observatory at Tokyo. If the weather is threatening additional observations are desired. In exchange, or this information the Observatory sends out wireless warnings to all vessels within range whenever a typhoon or dangerous cyclonic depression is reported, giving the position of the storm, barometric depth, and direction of movement. Reports are being received from a large number of vessels. Some of them come from as far east as the 180th meridian.

The New International Cloud Atlas.—Copies of the new edition of the International Cloud Atlas have been distributed. On the whole, this work is disappointing, as compared with the previous edition, published in 1896. The definitions of clouds have not been materially altered, except that *stratus* is now defined as "a uniform layer of cloud resembling a fog but not resting on the ground," in accordance with the decision of the International Meteorological Committee. Official status is given to the terms *cirrus uncinus* and *cirrocumulus*. English-speaking meteorologists will be astonished to learn, from this work, that the common English name of the *alto-cumulus* cloud is "great waves"! The earlier edition contained an "index of figures" in which was given the history, description and author of each of the paintings and photographs. This useful feature is unaccountably lacking in the new edition. Most of the colored plates of clouds are copied from the old edition, but are inferior in workmanship, on an average; and some of them are decidedly less characteristic pictures of the cloud-types depicted.

Does Your Engine Pound?

Pounding, misfiring, backfiring and premature explosions warn you to look for the hard carbon deposit caused by unsuitable oil.

In producing Polarine Oil we have practically eliminated the carbon-forming elements.

At the same time we have preserved its lubricating qualities.

Polarine does not break up or lose elasticity under severe friction.

It holds its "body" under extreme heat. It flows freely at zero.

Before the final product leaves the plant it must test up to the most rigid standards ever set for a gas engine lubricant.

On the road it has already demonstrated its high efficiency.

Polarine

The Polarine brand covers:

POLARINE OIL (in gallon and half gallon sealed cans, in barrels and half barrels), POLARINE TRANSMISSION LUBRICANTS, POLARINE CUP GREASE and POLARINE FIBRE GREASE.

These lubricants cover the needs of every part of the car.

Send to our nearest agency for "Polarine Pointers" which includes hints on the care of motor cars.

Standard Oil Company
(Incorporated)

Overland 30 H.P.

The Most Progressive Step in the History of the Industry

Five-Passenger Touring Car $900

THE introduction of our new five-passenger fore-door touring car (Model 59) at $900 is probably the greatest single manufacturing stride ever made in this or any other industry It is an industrial leap directly due to the remarkable and economical progress of a giant institution To start with this car is a real automobile—not a little frail cramped machine but a good big roomy car that is ample for five passengers And as a matter of fact it has more power than you will probably ever care to use The motor is the famous Overland type—4x4½—and will develop greater power than any other of a similar bore and stroke It has the fashionable fore-door body with door handles inside and with center control And what is more it is built right—having the strength of cars that cost twice the price

¶ In every respect it is beautifully finished The upholstering is of good leather stuffed with hair All trimmings are of the finest materials available This new model from every possible comparative standpoint is the greatest value for the money that has ever been placed on the market

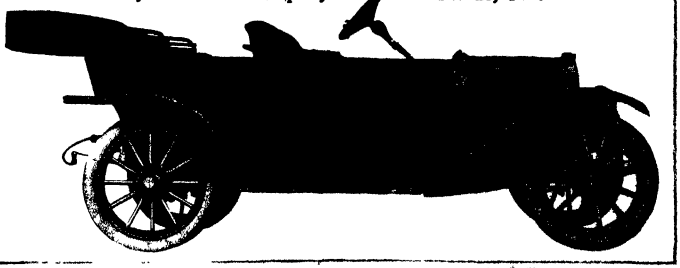
¶ People are apt to wonder why other manufacturers cannot equal this value It is for just this reason All manufacturing progress is due to better and larger manufacturing facilities the most efficient methods of handling men and the economical marketing of goods As any business increases its production costs decrease The larger a factory output becomes the better economical methods of manufacturing can be incorporated in the business

¶ Pins locomotives toothpicks or automobiles can all be made at less cost when manufactured in great quantities than if made piecemeal Materials—steel leather hair rubber etc—can all be bought at rock bottom prices if purchased in the greatest quantities These are existing commercial facts No man can dispute them

¶ The Overland plants are the greatest of their kind in the world We employ more men—use more labor saving automatic machinery and buy our raw materials in greater quantities than any other manufacturer Our output is 20,000 cars a year It costs about as much for the 5 000-car factory to sell its output as it does for the factory making 20 000 cars consequently the cost of each car of the 20 000-car factory is one fourth that of the 5 000 car factory and the man who buys an Overland pockets the difference

¶ The Willys Overland Company has no fixed indebtedness or bonds It has no heavy interest dates to fear The stock is *all owned by its president—John N Willys* He personally directs the entire organization

¶ We are positive that no other manufacturer today can produce this car and sell it at this price except at financial loss Write for catalog F27 describing this car It will be worth your while This year we have 9 body styles including runabouts roadsters small and large touring cars torpedoes and coupes Horsepower runs from 25 to 45 Prices $850 to $2000



The $900 car is made in two body styles—five passenger fore door touring car and two passenger torpedo roadster

Specifications

MODEL 59

Wheel base—105 inches
Tread—56 inches
Motor—4 inches by 4½ inches Cylinders cast separately L head type large valves valve springs enclosed in aluminum housings push rods lubricated insuring a sweet running silent powerful motor
Carburetor Model L Schebler (the best Schebler makes)
Transmission—Selective three speeds and reverse center control F & S annular ball bearings
Horsepower—30
Clutch—Cone
Ignition—Two independent systems Splitdorf magneto and battery one set of plugs
Brakes—Internal expanding external contracting on rear wheels
Springs—Semi-elliptic front three-quarter elliptic rear 1¾ inch wide
Frame—Pressed steel
Steering Gear—Worm and segment adjustable 16-inch wheel
Front Axle—Drop forged I section
Rear Axle—Semi-floating
Wheels—Artillery wood 12 spokes wide hub flanges
Spokes—1½ inch spokes bolt for each spoke
Tires—32-inch by 3½-inch
Mohair top and glass windshield $60 additional
Quick detachable tires—The most rational quickest operated longest-lived tires made

The Willys-Overland Company **Toledo, Ohio**

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are clear, the article good, and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately and in simple terms, the world's progress in scientific knowledge and industrial achievement. It seeks to present this information in a form so readable and readily understood, as to set forth and emphasize the inherent charm and fascination of science

The Coroner on the Bridgeport Railroad Wreck

As the result of his investigation of the recent wreck of an express train at Bridgeport, the coroner finds the New Haven Railroad guilty of "criminal negligence" in providing an unsuitable cross-over between the express and local tracks at the point where the disaster occurred. Although we agree with this finding so far as it attributes the wreck largely to the existence of a short cross-over, an opinion which is entirely in accord with our editorial on this subject in our issue of July 22nd, it is pushing the matter too far to designate the practice of the company as criminal.

Criminal negligence can be charged against a company only when it neglects to follow provisions for safe operation which have been established by law, or when it falls below the practice which has come to be regarded among the railroads as sufficient for safe operation. Judged by either of these tests, the New Haven cannot be held blameworthy. The use of short cross-overs between express and local tracks, or in locations where express trains running at full speed have to be switched from one track to another, is unfortunately very general in railroad practice. A few of the best roads, it is true, are alive to the danger; and, as we pointed out in the article referred to, one at least of them is revising its tracks by eliminating short cross-overs on main four-track roads when fast express trains may have occasion to cross from one track to another, but these are the exceptions and not the rule.

On the other point raised by the coroner, that it is inexpedient to use short cross-overs on lines over which express trains run, the coroner is entirely correct. The danger of a wreck through failure of the human element is so imminent, that we think the subject demands the immediate attention of the Interstate Commerce Commission, and the passage of a law requiring that such cross-overs be made of a proper length and the curvature of the turn-outs be made so easy that expresses can take them at high speed without danger of derailment. Although the cost of making these changes would be considerable, it would be well repaid by the greater safety which would be secured. Certainly, in cases like the Bridgeport wreck, where the cost of damages will prove to be enormous, the investment would prove to be good economy.

Solving Labor Questions in the Laboratory

AMONG the many methods proposed for the solution of difficulties between the employer and the workman, surely the most original is that suggested by Dr A Imbert, who, in a recent paper published in the *Revue Générale des Sciences*, proposes to apply laboratory methods to the solution of the wage problem. The author believes that physiology can furnish us with some precise information on the question of the ratio equivalence between work and pay.

Proceeding on the proposition that, in the work of a human or animal machine, the energy expended is produced by an increase in food above the amount which the organism requires when at rest, he makes the statement that the proper remuneration for work can be exactly determined, and this for the reason that it should correspond exactly to the cost of the extra food which made the work necessary.

The author considers the case of a postman who travels daily 35 kilometers on a bicycle in a level country, and who kept a record of the quantity and quality of the food which he consumed during a fortnight, the calorific value of which per day was calculated to be 3,200 calories. The day's work was estimated to be 140,000 kilogram-meters, corresponding to 330 calories of heat. Assuming a value of one-third for the efficiency of the human motor, Dr. Imbert determined that the postman's daily work required the combustion of an amount of food capable of furnishing 990 calories—an estimate which agrees very closely with one based on numerous physiological experiments showing that the human organism at rest requires daily on an average a quantity of food capable of furnishing about 2,300 calories. Now the difference between that and the 3,200 calories representing the value of his daily food as recorded by the postman gives a difference of 900 calories, which agrees fairly well with the 990 calories obtained by the first method of calculation. The mean equivalent may be taken as 945 calories.

The postman found that the cost of his food was 85 centimes a day, and from this it follows that the cost of his work was 25 centimes a day, instead of the four francs which he actually receives. It is evident that his pay should be based on something more than the monetary equivalent of the work done; the most selfish employer would concede that the pay should cover at least the 2,300 calories of food required by the man at rest, in addition to the 945 expended in work. Furthermore, he needs in addition to food, shelter and clothing, so that he should receive an additional allowance to pay for food, rent and clothing, items which are inseparable from any estimate of wages, even when they are considerd exclusively as remuneration for work done. The pay should provide for the support of the workman's family. Therefore, physiologically considered, the system of payment based on the monetary equivalent of the increase of food required is certainly inadequate, and the pay should be based upon an intelligent consideration of the general circumstances of the workman's life and surroundings and his reasonable expectation of comfort, recreation, family life and provision for old age.

A more direct application of laboratory methods was that made in the south of France, where hundreds of women are employed with pruning shears in cutting up long American vine shoots into cuttings suitable for planting. It is a mechanical operation, capable of exact measurements. By applying to the shears a simple dynamometer in the shape of a rubber bulb, Dr. Imbert measured the work done, by means of the travel of the fingers and the pressure exerted, the latter being recorded on a moving strip of paper. The cuttings are classed as large or small, according as their diameter is greater or less than six millimeters, and the pay is 60 centimes per thousand for the large cuttings and 50 centimes for the small ones. The women asserted that the difference of ten centimes was not sufficient, and they obtained an increase of pay.

From the paper tracings, Dr. Imbert found that for each centime of pay the worker exerted a total effort of 110 kilogrammes in cutting the small stems at 50 centimes per thousand, and a total effort of 266 kilogrammes per centime in cutting the large stems at 60 centimes per thousand. It was evident from these figures that the pay was not proportional to the work, and the experiments furnished an incontestable proof of the justice of the women's demands. For if fifty centimes was paid for the small cuttings, the pay for the large ones should have been 140 centimes instead of 60 per thousand.

Dr. Imbert claims that his system can be applied to a wide range of manual work, where the multiplicity of mechanical actions would seem to present an obstacle to experimental study of this kind. For instance, he used it successfully to determine the actual work accomplished in moving bags and bales with a hand-truck. The correctness of his conclusions would seem to be borne out by a comparison of the same work when it was done first with a truck and alternately then with a wheelbarrow, the wheelbarrow proving, of course, to be the more fatiguing medium. The article of Dr. Imbert which is published in full in the current issue of the SUPPLEMENT, will be found to repay a careful study.

Amazing Progress in Aviation

FOR the third time within the past three months a French naval lieutenant, who learned to fly only the first of the year, has won a long-distance cross-country race and demonstrated his prowess in airmanship. We refer to Lieut. Conneau, who, flying under the name of André Beaumont, has met with wonderful success in aviation. In the Paris-Madrid, Paris-Rome, the European circuit, and, lastly, the *London Daily Mail's* Circuit of Great Britain, Lieut. Conneau, flying a Blériot monoplane, has been among the leaders. In all but the first-mentioned race he has succeeded in finishing the winner.

All of these races have been from 900 to more than 1,000 miles in length, but the English circuit was the most difficult on account of the rule requiring the aviator to finish the race with the same aeroplane and motor with which he started and without the replacement of any of the essential parts. Three French monoplanes, piloted by two Frenchmen (Lieut. Conneau and Jules Vedrines) and one Englishman (Mr. Valentine) led the race from the start. Valentine was forced out after a gallant struggle and after he had completed half of the circuit, on account of a broken propeller; but his two competitors, because of their experience and training, finished the race without mishap and in record time. When the rules of this race were formulated it was believed that ten days would not be too long a time to allow for the completion of the circuit, yet despite the enforced rest made necessary by the rules, Lieut. Conneau and M. Vedrines completed the course in 3¼ 1-2 hours and 35 5-4 hours, respectively, and finished a week ahead of the time limit which had been set for the completion of the race. The actual time in flight of the French lieutenant was 22 hours and 28 minutes, corresponding to an average speed of 45 miles an hour, while Vedrines required an hour and 16 minutes longer, which reduced his speed to 42.8 miles an hour. The speed averaged by the winner in this race was about the same as the speed he made in the European circuit. The remarkable feature of the race was the fact that it was completed without mishaps or breakage of the machines, and distances as great as from New York to Montreal were covered at a 60-mile clip. The present race was for the aeroplane very similar to the "sealed bonnet" contests that were in vogue a few years ago for automobiles. It is interesting to note that a prize of $30,000 for the first aviator who should fly from New York to St. Louis—a distance of about 1,000 miles—even with a time limit of 100 hours, did not interest any aviators, American or foreign, when it was offered a year ago. It is doubtful even now whether this prize would attract any foreign aviator should it be put up for competition again. What is needed in America is a prize of $50,000 to $75,000 for a circuit race of 1,200 to 1,500 miles. If the Aero Club of America could organize such a race, it would show itself worthy of being the representative organization, and would encourage a development of aviation in a way that has never yet been done in this country.

Next to endurance in cross-country flying, the endurance of man and machine in a single flight is one of the most interesting questions. At the end of last year, Henry Farman attempted to remain aloft in continuous flight for a period of 12 hours. He actually succeeded in flying continuously for 8 hours and 12 minutes. Since then he has always been eager to increase his record to the half-day point. On July 21st, M. Loriden, in one of his machines, managed to fly continuously for 11¼ hours, during which time he covered a distance of 469 miles. It is claimed that he alighted on account of fatigue and not because his fuel was used up. On July 26th, at Mineola, St. Croix Johnstone, in a Moisant monoplane, made 39 circuits of a 5-mile course, covering 195 miles in 4 hours, 1 minute, 54 3-5 seconds, in an effort to break M. Loriden's record. He was obliged to descend on account of motor trouble, but he raised Parmalee's endurance record, made last January at Los Angeles, by 22 odd minutes.

The above achievements show the wonderful strides that are being made week by week in aviation and lead us to believe that within a very few years we shall have trans-continental and trans-Atlantic aeroplanes flying at faster speeds than the modern express trains.

Even at the present time express-train speed has been greatly exceeded. In the English circuit Lieut. Conneau flew the 348 miles from London to Edinburgh at sixty miles an hour and beat by a whole hour the fast "Flying Scotsman" express, while in the Paris-Madrid race Vedrines covered the 830 miles between Paris and Angouleme at the rate of 72

Eighty Years of Locomotive Practice in England

How the Old "Rocket" Compares with a Modern Engine

IN the accompanying illustration an interesting impression is conveyed of the development of the railway locomotive in Great Britain during a period of eighty years. Stephenson's famous "Rocket" is here shown in comparison with the latest type of London and Northwestern Railway passenger express traffic locomotive, "W. C. Brocklehurst, No. 2155," of the new "George the Fifth" class, and their juxtaposition affords a comprehensive idea of the remarkable strides that have been made in railway engineering upon British railways. The "Rocket" was built in 1829, and took part in the famous contest at Rainhill, when the directors of the Liverpool and Manchester Railway, now forming part of the London and Northwestern system, offered a prize of $2,500 for the purpose of deciding the question of the adaptability of steam locomotives for working railways. Five engines were entered in that classic competition, from which the "Rocket," as is well known, emerged victorious.

It is interesting to compare the weight and speed of the train in this competition, which may be regarded as the standard for those early days, with those of modern times. It was stipulated in the 1829 competition that the successful engine, if it weighed 6 tons, should be capable of drawing after it, on a level plane, a train of the gross weight of 20 tons, including tender and water tank, at the rate of 10 miles an hour, while the steam pressure in the boiler was not to exceed 50 pounds per square inch. In the actual trial the "Rocket" attained an average speed of about 19 miles per hour while hauling a train weighing 13 tons.

Stephenson's engine had a cylindrical boiler measuring 6 feet in length by 3 feet in diameter, with flat ends, having 25 copper tubes of 3 inches diameter. The firebox was 2 feet wide and 3 feet high. The cylinders, two in number, were 8 inches in diameter, and had a stroke of 16½ inches, while the diameter of the driving wheel was 56½ inches. The engine exerted about 20 horse-power, and weighed 9,296 pounds, while the tender weighed about 7,168 pounds. The latest London and Northwestern engine standing alongside is one of the latest types of express engines used in this company's express traffic. The two inside cylinders are each 20½ inches in diameter, and have a stroke of 26 inches, with a boiler pressure of 176 pounds per square inch, or three and a half times that allowed in the "Rocket." The boiler is 62 inches in diameter, with a barrel 141¾ inches long, fitted with a steam superheating arrangement by means of which the temperature of the steam is raised to 650 deg. F. before being used in the cylinders. The firebox is 7 feet 4 inches long by 4 feet 1 inch wide outside the casing. The coupled driving wheels are 81 inches in diameter, while the weight of the engine in working order is 133,064 pounds, and that of the tender 86,920 pounds, giving a total weight of 219,984 pounds. It is fitted with apparatus for picking up water from troughs while traveling at full speed, and has a tank capacity of 3,000 gallons, while it carries 7 tons of coal.

In order to test the power and capability of this type of engine, the first locomotive built, the "George the Fifth," made an experimental run between Crewe and Euston, 158 miles, with a train composed of a dynamometer car and 13 8-wheeled corridor coaches weighing 357½ tons, and with engine and tender weighing 454¼ tons. On the outward journey one stop was made at Rugby, the average speed between these points being 54 miles per hour, the highest speed recorded being 68 miles per hour. Between Rugby and Euston the average speed was 58¼ miles per hour, with a maximum of 73 miles per hour. The return journey from Euston to Crewe was made without a stop, which distance was covered from station to station in 2 hours 36½ minutes, giving an average speed of 60½ miles per hour, with a maximum speed of 78½ miles per hour. These speeds and weights compared with what the "Rocket" achieved illustrate strikingly the enormous progress made in one branch of railway engineering, and show the great facilities placed before the public for rapid transit from one point to another in these days as compared with the condition in the early days of British railways.

Stephenson's "Rocket," and the latest type of English locomotive (George the Fifth type).

A STUDY IN LOCOMOTIVE EVOLUTION

The Comets

DR. WILLIAM R. BROOKS, director of the Smith Observatory, and professor of astronomy at Hobart College, Geneva, N. Y., discovered another comet on the night of July 20th. Its position was right ascension 22 hours 18 minutes 40 seconds; declination north 20 degrees 57 minutes. The comet is in the constellation Pegasus, and is moving slowly in a northwesterly direction.

While not at present visible to the naked eye, it is a fairly bright telescopic comet, and its movements will be observed with interest. This is the twenty-sixth comet discovered by Prof. Brooks—a larger number than any other living astronomer has found.

The Kiess Comet.

A comet was discovered by Kiess at the Lick Observatory on July 6th in R. A. 4 h. 51 m. 51.8 s.; Dec. north 20 deg. 18 m.

An observation of this comet was obtained by Dr William R. Brooks at the Smith Observatory, Geneva, N. Y., on the morning of July 13th, in R. A. 4 h. 40 m., Dec. north 24 deg. 10 m., which shows the motion of the comet to be southwest. It is in the constellation Auriga, and on the last named date about 11 degrees south of Capella.

It is now a bright telescopic comet and has a visible tail.

Artificial Measles in Monkeys

MANY attempts have been made to cultivate the specific organism related to the cause of measles in the blood of such animals as are commonly used for experiments on serums and toxins, etc., but without success. About seven years ago an English experimenter tried in various ways to infect chimpanzees by injection of blood taken from a measles patient but got only negative results.

Within the last year Dr. John F. Anderson, Director of the Hygienic Laboratory, and Dr. Joseph Goldberger have carried on similar experiments with a number of rhesus monkeys. The blood used was drawn from measles patients. The monkeys showed rises in temperatures characteristic for this disease, and in a number of cases there were distinct eruptions on various parts of the skin. Two of the monkeys that showed distinct symptoms were held for the purpose of inoculating other monkeys, two new ones being inoculated from each. After a number of days, each of the monkeys showed definite reaction in temperature, one in each pair also showing an eruption of the skin. From these experiments it may be hoped that further research in the attempt to obtain anti-toxic sera for measles, or at any rate further light upon the nature of the disease, will be more profitable for treating the malady, than those of the past.

The "Electric Arc"

A Pioneer Electrically-propelled Ship

By the English Correspondent of the Scientific American

FOR some two or three years past there has been considerable academic discussion regarding the possibilities of propelling large vessels by an electrical system. Two Scottish electrical engineers, Messrs. Mavor and Coulson of Glasgow, who have devoted considerable attention to this problem, have carried theory to a practical stage, a special vessel having been built by the Dumbarton shipbuilding firm of MacLaren Brothers and equipped with the electric propulsion set which they have evolved for use with alternating current. Through the courtesy of the inventors we are enabled to describe the features and illustrate this interesting craft.

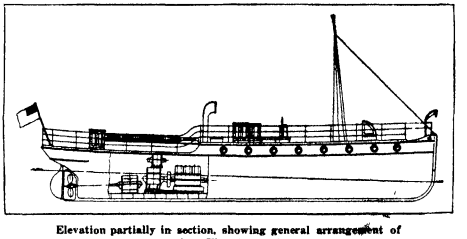
The vessel measures 50 feet between perpendiculars, has a beam of 12 feet, molded depth of 7 feet 4 inches; a maximum draft of 4½ feet, and is certified by the Board of Trade to carry fifty passengers. It has been christened appropriately the "Electric Arc."

The mechanical equipment is carried out on the lines set out by Mr. Mavor in his paper, read before the Institution of Engineers and Shipbuilders in Scotland in February, 1908, and before the Institution of Civil Engineers in December, 1909. It comprises a six-cylinder Wolseley gasoline motor developing 45 brake horse-power, driving an alternating current dynamo with its exciter, the propeller being coupled to an alternating current motor. The switch gear is operated from the deck, or from the engine room, as desired.

The inventors point out that although electric propulsion is not necessary or suitable for all vessels, yet in many cases it will form a convenient and economical addition to the power equipment of a ship. Hitherto electric transmission for marine propelling purposes has always been carried out upon the continuous current principle, but while this method is very convenient and suitable for small powers, its utilization offers serious difficulties in large installations. The inventors therefore maintain that alternating current motors alone are suited for the transmission of high powers at sea. They accordingly evolved their own lines upon which such should be applied, and the present large size model for actual practical experiments was constructed to demonstrate the possibilities and advantages of the system in regard to large vessels, and also to gain experience in details of application and handling of this equipment.

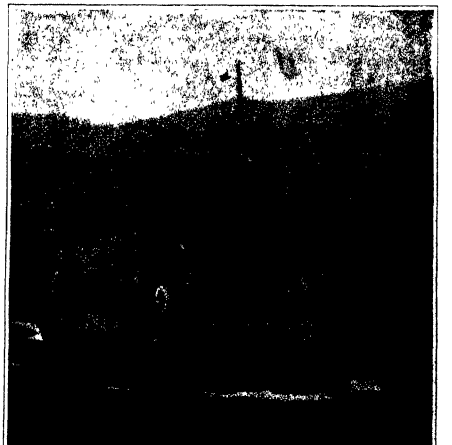
The motor has no brushes or slip-rings. It is of the type known as the "multiple wound machine," in which there are in the present instance two independent windings. The current used is alternating three-phase. The generator is designed to give two power-circuits to the motor, to represent the condition which would obtain more usually when larger powers were involved and where two or more generators would be in use for the full power.

The first combination of generator and motor windings gives full speed of 7.25 knots, and the second combination about two-thirds of full speed—about 5 knots. The power applied to the propeller is determined by the electric control, which in the present case is put in the hands of the navigator and operated from the bridge.



The first trials with the "Electric Arc" proved eminently successful. It was run over the measured mile in the Gareloch, the tests comprising the stopping, starting, speed-changing, reversing and maneuvering qualities of the vessel. The mean speed attained was 7.25 knots, with the propeller making 415 revolutions per minute. The current readings showed that about 25 brake horse-power was delivered to the propeller shaft at full speed, and that 35 brake horse-power was developed by the engine running rather below the rated speed.

The maneuvering capabilities of the boat were very strongly emphasized, the propeller being reversed from ahead to astern and *vice versa* time after time.



The reversing operations were equally striking, it being shown possible to throw the switch from "full speed ahead" to "full speed astern," *or vice versa*, without running any risk of damaging the machinery. Though such a sudden change would not be required in actual practice, it offered a severe test of the capabilities of the electrical system. The experiments are to be continued, and the success achieved so far has resulted in greater interest being centered in the possibility of adapting electrical propulsion to large vessels.

A BOAT PROPELLED BY ELECTRICITY

Fish Pastes Abroad

EXPERTS in the United States are giving careful study to the methods in vogue in certain fish factories in northern Europe, with a view to the economical preparation of products from fish that hitherto Americans have regarded as useless.

Among these is the preparation of fish-pastes from fish that have no commercial value either as fresh or salted food, but which, at the same time, possess a high nutritive value. It is said that the flesh of both the shark and the whale (which latter, however, cannot, of course, be properly classified as a fish) are largely utilized for the preparation of a fish-extract that resembles in some respects the popular extracts of beef, being at the same time far cheaper. All fishy flavor is eliminated by chemical processes, and the extract is valuable for the foundation of soups and in general cookery.

While meat is very nutritious, but its excessive amount of fat renders it unpalatable to most persons. To this fat is removed before the extract is boiled down to a syrupy consistence and sealed in jars.

In many of the fish factories of Norway a "fish-meal" is made that is eaten extensively by the nations of northern Europe. In these several ways fish which were formerly rejected as being unfit for food are being utilized to the advantage of many.

Trees and Men

IT has been calculated that a single tree is able through its leaves to purify the air from the carbonic acid arising from the perspiration of a considerable number of men, perhaps a dozen or even more.

The volume of carbonic acid exhaled by a human being in the course of twenty-four hours is put at about 100 gallons; but by Boussingault's estimate, a single square yard of leaf-surface, counting both the upper and the under sides of the leaves, can, under favorable circumstances, decompose at least a gallon of carbonic acid in a day. One hundred square yards of leaf-surface then would suffice to keep the air pure for one man, but the leaves of a tree of moderate size present a surface of many hundred square yards.

The Aviation Motor

Recent Developments in France

By Earle L. Ovington, Licensed Aviator

EMPLOYING the broadest possible classification, the science of aviation may be divided into two epochs—before man flew and afterward. The former might be called the Experimental Period and the latter the Practical Period. To be sure, at present there seems to be considerable discussion as to the exact line of demarkation separating these periods, but this resolves itself largely into a definition of the word "fly," as applied to the particular subject in hand. Lilienthal and other early experimenters with gliding machines undoubtedly imitated nature more closely than many later workers who used power-driven aeroplanes; but remarkable as were many of these early experiments, they did but pave the way for real man-flight, which may be considered to have been accomplished only when man left the ground with a power-driven sustaining surface, under more or less stable conditions. The object of the discussion which is raging so fiercely throughout the world of aviation at the present time is to ascertain who was the first to fly in a power-driven aeroplane, with the machine under the control of the operator, particularly as applied to lateral stability.

Any one who has given the subject even casual examination cannot but be impressed by the remarkable similarity of some of the more advanced machines of the Experimental Period as compared with many of the successful fliers of the Practical Period. Indeed, this similarity is so marked that the enthusiast seeks further for the cause, and has not gone far before he realizes that the development of the light and efficient internal combustion motor has done more than anything else to lift aviation from the experimental stage to that of practical man-flight.

In the automobile field we find a parallel state of affairs. Clumsy self-propelled steam vehicles existed years before the brilliant inventions of De Dion and Daimler gave to the world the wonderfully light and comparatively simple prime mover which has made the automobile the universally successful vehicle it is to-day. It is the same with the aeroplane. Examine Langley's man-carrying machine, which unfortunately was never properly tested, and the large, ingeniously constructed aeroplane of Sir Hiram Maxim, not to mention other models of early experimenters, and one is impressed by the enormous handicap they labored under in not having a simple, light motor.

In the early development of the aviation motor, extreme lightness was the object sought for, and was at first obtained only at an entirely disproportionate sacrifice of efficiency and reliability. Fortunately for aviation, however, the development of a suitable motor did not have to start from the heavy, stationary gas engines, for at the dawn of the Practical Period in aviation the automobile engine had already reached a comparatively high state of perfection. Designers of aviation motors at first simply took the more advanced types of automobile motors, and, adhering to their general design, eliminated weight by reducing the factor of safety of each member to the lowest practical point, and by employing the very highest grade of material and workmanship. The Antoinette motor which proved so successful in racing motor boats and the early aeroplanes, is a sample of this type. And it speaks well for Monsieur Levavasseur, the designer and constructor of this motor, that even to-day, in spite of the fact that the latest type of motor differs little from the earlier models, the Antoinette engine is considered in the foremost class among aviation motors.

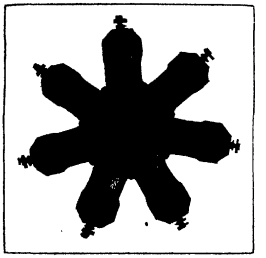

Fig. 1.—The new 70-horse-power Gnome motor.

At the present time, extreme lightness for a given output is as much sought for in aviation motors as it was in the first stages of development of the practical aeroplane. But this is due largely to the fact that an artificial state of affairs exists in the development of the aeroplane by the world's greatest designers and builders. During the Experimental Period of aviation, man was satisfied to progress slowly and along rational lines. Theory was far in advance of practice. During this period Langley, Lanchester and Maxim gave to the science of aviation their unparalleled researches, not to mention the works of less known writers. But from the moment man really flew, Practice vanquished Theory, and designers proceeded along almost entirely empirical lines to develop a flying machine for exhibition and racing purposes. From the opening of the Practical Period to the present time designers have been too busy actually building machines to meet the comparatively enormous demand, to worry very much about the theoretical side of the subject. Very great progress has been made, to be sure, but it has been largely confined to making the machines stronger and faster, and in standardizing, to a certain extent, the several types.

The demand for a light aeroplane for exhibition purposes, and a fast one for racing, has forced the designers of aviation motors to tax their inventive capacities to the utmost in an effort to produce a motor of the greatest possible power for a given weight. And when it is considered that there now exists a motor which weighs only about three pounds per horse-power, which has run continuously over eight hours in actual flight, we can get an idea of the wonderful strides made in the development of the aviation engine.

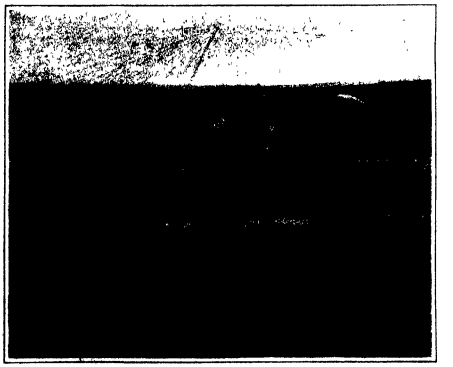

Fig. 2.—Bleriot 1911 model fitted with the 70-horse-power Gnome motor.

Although to-day lightness and speed seem to be the greatest aims of the designer, the time is not far distant when extreme reliability and high efficiency will be the objects sought for. By its very nature an aeroplane remains in the air only so long as it is moving rapidly forward, and a properly working motor is necessary for this condition, hence reliability without any question whatever, is the first essential in an aviation engine, assuming, of course, that the motor is light enough for the purpose. Duplicate power plants, or possibly a smaller power plant for emergency use, will do much to add to the security of aerial travel, but even under such circumstances the motive power should be as reliable as it is possible to make it. And as we understand more fully the design of the supporting surfaces in an aeroplane and the engineers more fully appreciate the desirability of reducing head resistance to a minimum, great power in a light

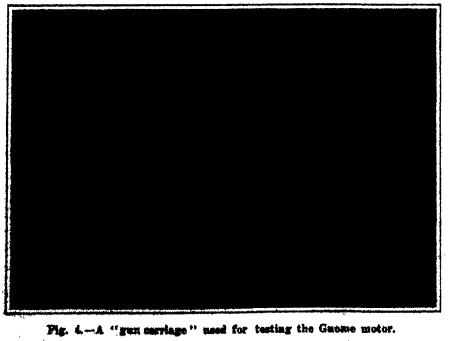

Fig. 4.—A "gun carriage" used for testing the Gnome motor.

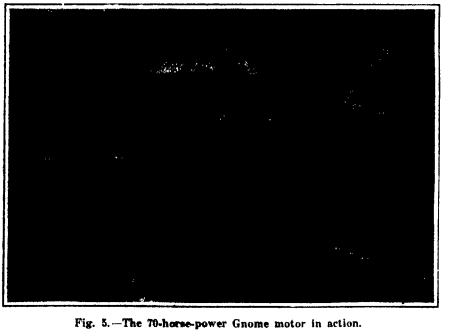

Fig. 5.—The 70-horse-power Gnome motor in action.

THE DEVELOPMENT OF THE AVIATION MOTOR

weight will become of less and less importance The designer of the little Nieuport monoplane made giant strides in this direction when he produced a machine carefully calculated to reduce head resistance This machine although fitted with only a 30-horse-power motor, almost equaled the speed record made by Leblanc at Belmont Park with his fourteen-cylinder, 100-horse power, Gnome-driven Blériot

Birds sent for hours under propitious circumstances with practically no expenditure of energy, and even under very adverse conditions fly with an efficiency which should make the intelligent aeroplane designer drop from his self-erected pinnacle as "conqueror of the air, and realize how poor indeed, from the standpoint of the natural fliers, is his flying machine

Aviation motors may be broadly divided into two general classes—reciprocating and rotary motors In the former the cylinders and crank case remain stationary while the crank shaft rotates, and in the latter type the crank shaft is stationary while the crank case and cylinders revolve around it All automobile engines and most aero motors, are in the reciprocating class, while the Gnome is by far the most prominent engine in the rotary class

It is interesting to note the various and often ingenious expedients adopted by the leading manufacturers to attain the same end, i e, the production of a light motor The designer of the Anzani reciprocating engine, who was one of the very first to devote his time to the production of a practical aviation motor, developed his product from the power plants he used on his motorcycle pacing machines His first engine was a three-cylinder one, having the cylinders all in one plane and arranged radially around the crank case By this arrangement he was able to use a crank case for three cylinders which was only slightly larger than that for one With this motor, rated at 25 horse-power, Blériot first crossed the English Channel, and in spite of the remarkable strides which have been made in more powerful aero motors, this original type of Anzani, almost unchanged, is to-day one of the most reliable engines made, and is the one used by Blériot and other leading manufacturers in their aeroplanes made for school purposes The writer, who obtained his French *brevet de pilote-aviateur* at Blériot's school at Pau, France, was surprised at the enormous amount of abuse these little motors stood without *materially* losing their power Anzani's latest product is a six cylinder, star-shaped motor of the same type, which somewhat resembles in appearance, when stationary, the rotating motor so much used in French aeroplanes

The R E P reciprocating engine, the product of Robert Esnault-Pelterie is another motor of this class where the cylinders are arranged radially around a common crank case The designer has carried this principle very much further, however, than any one else, for the writer saw last February, at the factory near Paris, a new R E P engine having no less than ten cylinders

In the Antoinette engine the factor of safety has been reduced to a minimum and made as uniform as possible for the component parts, by the use of the very highest class of material and workmanship Every little detail has received the attention of its experienced designer, Monsieur Levavasseur and most ingenious are some of the structural details The flywheel for instance which ordinarily is by far the heaviest member of an engine, in the Antoinette is simply a steel rim connected to a central hub by a flange of very thin and flexible steel When the motor is building up its speed, this flange is so flexible the whole flywheel seems "out of true" but at normal engine speeds centrifugal force is sufficiently strong to make the flywheel as rigid as if it were the usual heavy cast affair. In the Antoinette flywheel almost every ounce of weight is where its effect is greatest—in the periphery Other equally novel artifices are employed in order to reduce weight

Among American engines of the reciprocating class the Curtiss is probably the best known and most widely used Curtiss, like the designer of the Antoinette, has carefully studied every part of his design and produced a motor remarkably light and efficient It was with this motor in his own aeroplane that Curtiss won the first Gordon Bennett race at Rheims, France, in 1909, triumphing over the best European productions.

The question has yet to be definitely settled among designers of reciprocating engines as to whether cooling by air or water is the most desirable for aero engines Of the engines mentioned, the Antoinette and Curtiss use water cooling, while the Anzani and R E P depend upon air It is perhaps significant to note, in this connection, that the Renault motor is air cooled, while the famous automobile engine, made by the same concern, is cooled by water circulation Simplicity being such a desirable point where reliability is sought for, and reliability being such an essential in the aviation motor, the writer strongly favors the air-cooled motor, even for engines of the reciprocating class.

We now come to the consideration of what is undoubtedly the most interesting and promising type of internal combustion motor to-day—the rotary engine The designers of this comparative newcomer made a giant stride into the unknown when they entirely

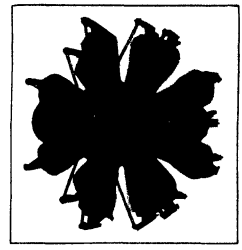

Fig. 6.—The 100-horse-power fourteen-cylinder Gnome, as used by Leblanc and Hamel in the recent International Cup race.

A 7-cylinder, 70-H P. engine on a Nieuport monoplane won the race

reversed the operation of the component parts of the gasoline engine Incidentally, in doing so, they banished forever certain inherent difficulties found with motors of the reciprocating class

In the ordinary reciprocating motor, the cylinders, whether air or water cooled, are stationary, as is the crank case, while the crank shaft revolves In the rotary motor, the crank shaft is the stationary member, while the cylinders, arranged radially and air cooled, rotate with the crank case around it. As there is to-day only one representative of the rotary class, which has universally proved its right to be classed as unquestionably reliable, we will confine our remarks to that particular make—the wonderful Gnome rotary motor

Fig 1 is the very latest product of the Gnome factory—the new 70 horse-power. Fig 2 shows the writer's 1911 model Blériot, fitted with this motor, it being the first machine sent out from the Blériot factory employing the motor of 70 horse-power, and the first Blériot with the new "inverse curve" tail brought to America Comparing the 50-horse-power and the 70-horse-power engines, the method of attaching the cylinders to the crank case has been greatly improved. In the case of the 50 horse-power it requires a mechanic of the highest order, who knows the Gnome motor thoroughly, to dismount and assemble it, but with the new 70 horse-power it is necessary only to unscrew a few nuts when the front half of the crank case may be removed, leaving the cylinders readily detachable. The method of clamping the cylinders, too, is far more secure than in the older model.

The writer spent a most interesting afternoon going over the Gnome factory, which is just outside of Paris, with Monsieur Seguin, the chief engineer. This factory is literally engaged in turning out steel shavings, for every part of the entire motor is turned from the solid metal. In the rough the cylinders are drop-forged nickel-steel bars; but when the lathes and boring tools have completed their work, they are engine cylinders with radiating fins as thin as paper and walls not much heavier. It is interesting to note, in speaking of the Gnome cylinder construction, that the receptacles into which the spark plugs screw are internally threaded steel tubes welded into the side of the cylinder head by a secret welding process, the arrangement being shown in Fig. 3. The crank shaft is hollow, and through it pass the gasoline vapor and oil for lubrication. The construction is indicated in Fig. 3, the carbureter being plainly visible at the end of the shaft, while the oil pipes enter the shaft from above as shown. Just to the left and below the oil pipes may be seen the pumps which force the fuel and oil under pressure to perform their duties.

The vapor from the carbureter, after passing into the crank case through the hollow crank shaft, is admitted to the combustion space in the head of the cylinders through automatic inlet valves which are balanced by counter weights to eliminate the action of centrifugal force. The wonderful ingenuity of construction of these valves, making them easily removable through the cylinder head without the necessity of taking down the engine, must be remarked upon.

The exhaust valves are of course mechanically operated, the construction being clearly evident by an examination of the illustration

The magneto is behind the mounting framework in Fig 3, while the segment bearing part of the distributer rotates, and from the segments wires lead to the spark plugs, as clearly indicated.

Fig 4 shows one of the testing "gun carriages" in use at the Gnome works, with a motor in place Fig 5 gives an idea of the appearance of this wonderful motor in action, while Fig. 6 is a view of the 100-horse-power engine with fourteen cylinders This is the motor used by Leblanc and Grahame-White when the latter won the Gordon Bennett race at Belmont Park last fall.

The writer has made a deep study of internal combustion motor design, and is firmly of the opinion that the rotary engine is the aviation motor of the future, not to say the present The Gnome motor to-day holds practically all the world's speed records, which is remarkable when the handicap in favor of the reciprocating engine from the standpoint of time taken in development is considered.

In the case of the rotary motor, the cylinders and crank case serve as an efficient flywheel, thereby eliminating dead weight which is of no other use on the reciprocating engine. Vibration, due in the reciprocating engine to the unbalanced moving parts, is practically done away with in the rotary motor. With the rotary cylinders, water cooling, with its additional weight and complication, is not even thought of, for the rapid movement of the cylinders themselves through the cooling medium is all that can be desired A closer examination of the two types emphasizes many other advantages of the rotary motor, such as a reduction in size and weight for a given power, reduction of the number of bearing surfaces, etc.

The principal disadvantage of the rotary motor at present is the fact that castor oil is the only lubricant which has been found so far to be satisfactory, and on account of the nature of the oil used, comparatively large quantities must be employed. Critics have even called it "the oil-cooled motor." Furthermore, the use of this oil in such large quantities (varying from one part of oil to three or four of gasoline) makes frequent cleaning necessary. In spite of this, however, the Gnome engine has forced its way to the front rank, against the adverse criticism and even abuse which has always stood in the path of true progress, until to-day it is the engine above all others where the greatest power and reliability are derived for the least weight. The idea of the writer in speaking so forcibly of the superiority of the Gnome motor is to awaken engine designers in America to the evident superiority of the rotating type over the reciprocating, with the hope that American manufacturers will attack the problem of rotary motor design, and, with their characteristic ingenuity and enterprise, produce an American aviation engine which will stand second to none. The rotary motor of the Gnome

Fig. 3.—View of side and rear of the new 70-horse-power Gnome.

THE DEVELOPMENT OF THE AVIATION MOTOR

type is the nearest approach yet made to the ideal internal combustion engine—the gas turbine—and as such demands recognition by every American manufacturer. Incidentally, the writer has heard on good authority that the Gnome company are experimenting with a two-cycle engine of the rotary type. Since the proper cooling and scavenging of the cylinder of this class of motor are the two hitherto almost insurmountable obstacles, it would seem the rotary principle is particularly adapted to the development of this class of engine.

The Tallest of Tall Buildings

WORK is now in progress at Broadway and Barclay Street on the foundations of one of those huge steel-and-concrete office buildings, which are such a characteristic feature of the modern architecture of New York city. The Woolworth building, as it will be called, will have a frontage of about 155 feet on Broadway, between Barclay Street and Park Place, and it will extend into the block for a depth of about 200 feet. Its most distinguishing characteristic, at least to the popular eye, will be its great height, for its crowning element, ball or lantern, or finial, or whatever it may be called, will stand exactly 775 feet above street level.

At the site there is the characteristic deep bed of quicksand, and through this the foundations are now being carried down everywhere to solid rock, which is about 110 feet below the sidewalk. Hence the structure, from lowest foundation to its topmost point, will have a total height of 885 feet.

The main building, which will cover the whole area except for a 35 by 96 foot interior rear court, will contain 31 stories, and above this there will rise from the center of the Broadway façade a great tower, 84 by 86 feet square, which will extend, with vertical walls, to the 50th floor, with an offset at the 42nd floor, where the dimensions are reduced to 69 by 71 feet, and at the 47th floor, where there is a further reduction to 59 by 61 feet. The height from the sidewalk to the 31st floor, which marks the top of the main roof, will be 400 feet. The tower extends another 370 feet, from the 31st to the 50th floor, making the height above sidewalk to this point 670 feet. Here it is surmounted by a pyramid which is 54 feet square at the base, in which are five additional floors and an observation gallery, the last-named being at an elevation of 730 feet above the sidewalk. There are two floors below street level, and the general height of each story throughout is 12½ feet. The Woolworth Building is designed in accordance with the Building Code of this city, which allows 150 pounds per square foot load on the first and basement floors and 75 pounds per square foot on each of the other floors. When we remember that a uniform wind pressure of 30 pounds per square foot over the whole surface of the building has been provided for, it can be understood that the stresses from wind alone reach enormous figures. The maximum direct compression from wind pressure on one single column of the building reaches 2,500,000 pounds to which must be added 200,000 pounds delivered from the portal bracing.

The steel framework alone will contain 20,000 tons of steel. Its various columns will be supported on 69 piers of partly reinforced concrete, which are now being sunk to solid rock at an average depth of 110 feet below street level. Except where conditions call for rectangular shapes, the caissons are cylindrical, and they vary from 8 feet 2 inches to 18 feet 9 inches in diameter. They are loaded to a maximum of 18 tons per square foot. Generally speaking, the axes of the columns stand in line with the axes of the caissons, but in some cases they are placed eccentrically, and their load is transferred to the center of the caisson by means of heavy steel girders acting as cantilevers. These girders are very massive and stiff, being as much as 2 inches in thickness in the web, and having an average depth of 8 feet, with a maximum weight of 60 tons.

From the 55th to the 50th floor, the inclined members of the pyramid take care of the wind stresses. From the 50th to the 47th floor, deep floor girders with solid gusset plates serve the same purpose. From the 42nd to the 28th floor, the exterior wall columns are braced against the wind by extra deep wall girders, and by knee braces, reaching well in to the center of each story. From the 28th floor to the street, every panel between the outside columns facing Broadway and the opposite face of the building is stiffened by a full-depth web portal with heavy flanges. Transversely to Broadway, the bracing is by means of single portals, reaching across the full width of the tower.

There are in the building 60 main columns of closed box section. The maximum load on a single column reaches the enormous figure of 4,750 tons, and this column measures at the base, 2 feet 6 inches by 3 feet 8 inches, the total cross section of metal being 650 square inches. The architect of the building, Mr. Cass Gilbert, and his consulting and designing engineer, Mr. Gunvald Aus, are to be congratulated on the design. The SCIENTIFIC AMERICAN has frequently suggested that for good architectural effect it would be advisable, in these tall buildings, to accentuate the vertical lines at the expense of the horizontal. Mr. Gilbert has done this to a marked degree, and in his treatment of the tower he has introduced those open-work pinnacles or 'towerettes," if we may coin a word, which the medieval builders used to such happy effect in the towers of their Gothic cathedrals.

The exterior walls are to be built of granite up to the fifth floor, and above that of terra cotta. The building will be served by 26 elevators, all of which will be thoroughly fireproofed, also there will be four commodious fire-escape stairways, widely separated from one another, and each built in a fireproof shaft. The structural steel will have a coating of one inch of cement mortar, their interior spaces will be filled in solid with concrete or mortar, and the whole will be inclosed in a shell of terra cotta 3 inches thick. There will be no wood whatever nor any inflammable substance in the building. Doors, windows and trim will be of pressed steel, floors of mosaic, and exposed exterior windows will be glazed with wire clamps.

Correspondence

[The editors are not responsible for statements made in the correspondence column. Anonymous communications cannot be considered, but the names of correspondents will be withheld when so desired.]

Our Merchant Marine.

To the Editor of the SCIENTIFIC AMERICAN:

The issue of the SCIENTIFIC AMERICAN for July 15th was very interesting. The suggestions for restoring the American merchant marine run on the old lines, viz., differential duties or subsidies. Free ships are anathema.

Mr. Sulzer believes that differential duties on goods brought in by American steamers will restore the American flag to the deep-sea trade. He bases it on the fact that up to 1828, differential duties freighted in American ships were in effect.

The fact is ignored that, although after 1828 the differential duty law was no longer in effect, as stated by Mr. Sulzer, our shipping continued to grow until at the time the civil war broke out we were a close second to Great Britain in shipping.

Why we grew in shipping till we had almost overtaken Great Britain and were fast outstripping her is not touched upon; no mention is made of the fact that we had the natural resources in abundance, i. e., timber of the best quality that grew down to the edge of the ocean. This naturally stimulated a seafaring people to build ships. The ventures were successful; shipping grew, free from the building traditions of the old world, new types were, in the course of time, evolved, that were not alone marvels of beauty, but great deadweight carriers as well; and for speed they had no equals among the productions of European yards.

Is it any wonder, then, that shipping in the United States grew so fast, that the supremacy of Great Britain as a shipping nation was threatened?

In those days there was no cry that shipping was unprofitable; the Stars and Stripes were seen in every sea, and we traded every country on the globe. Then came the civil war and the transfer of our ships to foreign flags; later the introduction of the iron-built steam tramp, and gone was the occupation of the wooden sailer, and the grass grew in the shipyards of Massachusetts and Maine.

Yet to-day the United States makes more iron and steel than Great Britain and Germany together. On the authority of iron and steel manufacturers, we manufacture it cheaper than anywhere else in the world. We have shipyards that can turn out as good ships as can be turned out anywhere in the world. With all these advantages, we are told that we cannot build as cheaply as can builders abroad.

American capital is furnished to build steamers in foreign shipyards, and many of these steamers are built from plates exported from this country.

In spite of this, Mr. T. G. Roberts, naval constructor U. S. N., apparently believes that an adequate merchant marine can be built up only by discriminating duties and subsidies. In his mind the results of a free-ship bill would only result in "splendid imaginary shipping." The shipping owned by Americans is not at all imaginary, there are many millions of dollars invested in shipping running under foreign flags, application has been made to Congress for the privilege of placing some of it under the American flag, but permission is withheld. Why?

And yet, Mr. Roberts states in the heading of his article, "The Merchant Marine as an Auxiliary to the Navy," the navy would need some nine hundred merchant vessels to draw from in case of war.

Allow that our coast yards could turn out fifty 5,000-ton steamers annually, it would take something like eighteen years to build them, and it is not to be supposed that our navy will stand stationary during that period; neither does he take into account the annual growth of commerce and the consequent need of new tonnage annually.

Several fleets now operated under foreign flags are owned by Americans, and in case of war foreign governments could take them as auxiliaries to their navies. It seems but wisdom to allow such tonnage American registration. If Americans will not avail of the privilege, then it may become necessary to take further measures to insure American tonnage under the American flag.

The passage of such a measure might mean the avoidance of a great deal of trouble in the future. Even though foreign flags fly over American-owned tonnage, it may be expected that American owners will look to the United States Government for aid, should their investments be seriously threatened, and it would be no source of gratification to Americans in case of war, to find the tonnage for which we furnished the capital used in conjunction with a foreign navy to subjugate us.

Congress has just passed a reciprocity treaty with Canada covering farmers' produce. We can enter reciprocity with Great Britain in shipping by passing a free-ship bill. Great Britain now allows American-built ships British registration when owned by British citizens. Let Congress enact a law granting American registration to American-owned British built ships for the Philippine and foreign trade only.

Chicago, Ill. CHARLES DEPSEY.

Observation of the Kiess Comet

To the Editor of the SCIENTIFIC AMERICAN:

The Kiess comet was observed here early on the morning of July 20th, 1911, by the writer, with a 3-inch refractor. As it is equivalent to about the seventh magnitude, and easily visible through a small telescope, it should be perceptible even in an opera glass. It is rather small, though bright, and resembles a nebula, and is moving in a southwestern direction. At about 2 15 A. M. on July 20th it was approximately 4 degrees west and a very little to the south of the star Iota Aurigae, which is of the third magnitude and not far from Capella, so can be easily located from this object. The position of the comet on July 12 8412 G. M. T. was R. A. 4 h. 41 m. 35.2 s., Dec. + 31 deg. 19 min. 20 sec.

Berlamont, Mich. FREDERICK C. LEONARD.

Why Left-hand Plows are Used in the Middle West

To the Editor of the SCIENTIFIC AMERICAN:

In the issue of the SCIENTIFIC AMERICAN for June 17th 1911 in "Notes for Inventors" I note the comment on the extensive use of left-hand plows in southern Ohio, Indiana and Illinois. The explanation of such use is found in the fact that these localities were largely settled by people from Southeastern Pennsylvania, Maryland and southward, in which latter localities it was and is to a large extent, yet customary to drive two or even four horses with a single line, the line being attached to the left-hand or "near" horse only, the "off" horse being guided by a "jockey stick," one end of which is tied to his bit and the other end to the "near" horse's hame or collar. In plowing with such an arrangement it would obviously be necessary to place the guiding or "near" horse in the furrow, which would necessitate the use of a left-hand plow.

The custom of single line driving has probably been largely abandoned in the above first-mentioned localities, owing to the extra effort and time required to train the horses, but the use of left hand plows has continued, and probably will continue indefinitely, due to the fact that each generation learns to plow with the tools of its elders, and having once learned with a left-hand plow, the change to right-hand is not easy.

Historical and Popular Exhibits at the International Hygienic Exposition in Dresden

TWO of the most interesting departments of the International Hygienic Exposition which is being held in Dresden are the historical and popular sections. In the historical section the history of hygiene is illustrated by numerous models and pictures, as well as by other means, and similar methods are employed in the popular section, the purpose of which is to give the average visitor a clear and non-technical presentation of the progress of hygiene and to impart some practical information concerning the laws of health.

Illustrations and descriptions of some of these exhibits are here reproduced from a recent issue of the *Illustrirte Zeitung*, which is filled with interesting matter relating to the exposition, to which it is entirely devoted.

In the historical section the visitor is enabled to review the progress of hygiene from the infancy of civilization to the present day. The record is very incomplete, and is made up of fragments laboriously unearthed by the archæologist, for the writers of history and the makers of monuments deal almost exclusively with wars and kings, and devote little attention to the life of the people.

We know from excavations that the Celts and Germans, before they came into contact with Roman civilization, lived in caves and cellars, and the human bones found in these underground dwellings show that gout and rheumatism were very common, as might be expected. The inhabitants of the upper Nile region were also grievously afflicted by gout.

These northern tribes, after the primitive age of furs and skins, wore close-fitting breeches and sleeved shirts of thick wool, in striking contrast to the light and flowing garments of the Romans and Greeks (Fig. 1), and in entire accordance with the difference in climate.

The disposal of the dead is a subject of great hygienic importance, and is well illustrated in the historical section. Although cremation, embalming and the sealing of corpses in tight oaken coffins, stone sarcophagi (Fig. 2) and vaults, were probably not adopted for hygienic reasons, they produced hygienic results, especially in view of the widely prevalent custom of keeping the remains of diseased members of the family very near or even in the house.

Among other customs of hygienic value but non-hygienic origin may be mentioned bathing, which in many lands was regarded as a religious, rather than a hygienic duty.

Again, the ritual requirement of perfect health in animals which were offered in sacrifice (and which by the way, often constituted the only animal food used) was firmly established among the Babylonians, Egyptians, Jews and Greeks, ages before there was any official inspection of slaughter houses.

Hygienic motives, however, were consciously followed by the Greeks, Romans and other ancient peoples in house building, paving, draining, sewerage, water supply, the construction of private and public baths, and in many other things. An ancient Babylonian drain is illustrated in Fig. 3, while Fig. 4 shows a model of the outlet sluices of the Alban Lake.

Two institutions of great hygienic value originated in Mesopotamia and were brought to Europe by the Jews: the weekly day of rest and the isolation of diseased persons. In the Middle Ages the precepts of Leviticus were developed into a system of sanitary regulations which, in a desperate warfare waged for

EXHIBITS AT THE INTERNATIONAL HYGIENIC EXPOSITION, DRESDEN

centuries, finally defeated the dreaded Asiatic invader, leprosy. Fig. 5 shows a rattle used by the leper to give warning of his presence.

The epidemics of the plague, and especially the black death (1348-1350) led to the establishment of municipal and state quarantine and other preventive measures which are still employed. The Romans had small military hospitals, but general hospitals, leproseries and pest-houses (Fig. 6) originated in the Middle Ages.

The characteristic German fondness for bathing was freely indulged even in the Dark Ages, when every village had its Turkish bath. The fashion prevailed, not without abuses (Fig. 7) throughout the Middle Ages, but waned in the seventeenth century in the general depression caused by the Thirty Years' War. In the eighteenth century the "return to nature" which followed the French Revolution led to a resumption of the practice of bathing in streams, which had previously been prohibited as unseemly. At that time hygiene was earnestly studied in France, the war against the corset was inaugurated, and, in 1802, a general council of health was founded. During the same period Jenner, in England, introduced vaccination, which in a few decades put an end to the frightful epidemics of smallpox which had long ravaged Europe. The epidemic of cholera in England in 1831 contributed greatly to the promotion of cleanliness and of hygiene in general.

These are a few of the subjects that are copiously illustrated by the historical exhibits of the exposition, which also show the hygienic progress that has gradually been made in house building, cooking, heating, lighting and clothing, in the installation of prisons, barracks and abattoirs, in travel by sea and land, etc. Fig. 8 shows a model of a chimney such as was used in underground dwellings after the need of such a device had at last become apparent, and Fig. 9 exhibits a diversified assortment of mediæval and modern foot gear.

Few people appreciate the great boon of health until it is lost or seriously impaired. This fatalistic indifference is explained by the general ignorance of hygienic laws. Great advances have been made in physiology in the last few decades, and the cause and the means of prevention, if not of cure, of nearly every disease are known by physicians, but very little of this knowledge has reached the mass of the people. The popular section of the Hygienic Exposition is designed to impart this knowledge in such a form that it can be understood at a glance. The attentive and intelligent visitor will leave this section impressed with the wonderful complexity of the body and the value of good health, and filled with the resolve to preserve this precious gift with jealous care. EXHIBITS AT THE INTERNATIONAL HYGIENIC EXPOSITION, DRESDEN

little detailed description of this section that can be given in this article will best be presented in connection with the few illustrations here reproduced

Figs 10 11, 12 and 13 relate to water and its impurities Fig 10 shows an open well lined with a wall of stone and situated near a farmhouse and stable Not far off is the village pond, on the shore of which stands a small slaughterhouse The water of the pond filled with impurities derived from the slaughterhouse, the washing of clothes and many other sources seeps through the soil to the "ground water" which supplies the well Other water carrying impurities from the stable and dung heap, drains, etc, enters the well through fissures in the wall, and dust and other things fall into the open mouth, so that the well water is necessarily impure, and may contain germs of typhoid and other diseases The conditions shown in Fig 11 are little better The well is covered and provided with a pump, and is apparently protected from surface impurities by the impervious stratum of yellow loam which it traverses in its descent But the wall and the wooden cover of the well in time develop fissures which admit impure water from the ditch at the left and from other sources Moreover, a cesspool (shown at the right) of later and very faulty construction, also penetrates below the stratum of loam, and directly contaminates the ground water Such wells often cause epidemics which are carried through a whole village in various ways, for example, a careless baker who allows a washerwoman to test the freshness of his bread by squeezing the loaves with her wet hands

The pump well shown in Fig 12 is apparently well protected by layers of cement and clay, and the cesspool is made tight by the same means, but the ground water is contaminated by neighboring sources of impurity

Fig 13 shows a deep pipe well, driven through one stratum of yellow loam and two of blue clay The water is thoroughly protected from contamination from the surface above and near it, and is probably pure

Various types of dwellings are illustrated in Figs 14 and 15 Beginning at the left of Fig 14, the first drawing shows an ancient Hebrew house, which consists essentially of a high wall inclosing an open night shelter The second dwelling is the primitive hut of the Indians of the Amazon consisting merely of a roof placed on the bare ground without walls The third picture shows a model of a farmhouse in Saxony, with the roof turned up to show the interior The sleeping- and living rooms kitchen (usually chimneyless), barns and stables are all under one roof and within one wall, in defiance of the most elementary hygienic requirements The fourth dwelling is a Canadian Indian wigwam The tent is one of the most primitive of human dwellings, and is found chiefly among hunting and nomadic tribes The open top of this Indian tent is provided with flaps to control the outflow of smoke Behind the tent is shown a fence which serves as a wind shield, and to right and left are stacked the sledge poles on which the tent and other possessions are carried on journeys The fifth and last dwelling shown in Fig 14 is an African Herero hut, consisting of an inverted plaited basket, like an old fashioned beehive, plastered with clay and cow dung The first (left hand) drawing in Fig 15 represents a vertical section of a Point Barrow Eskimo hut built of logs and covered with snow as a protection against cold The hut is entered by creeping through a low doorway The second picture shows an Italian peasant's house The interior is dark and uncomfortable, the windows are not glazed, the roof is flat, and is a favorite evening resort The third picture shows an ancient German hut, built of tree trunks wattled with brush Huts of this type are still used by primitive tribes in various parts of the world The fourth picture shows a prehistoric German earth dwelling consisting of a pit surmounted by a dome of brush covered with clay or moss The fifth and last picture shows a farmhouse in the German Schwarzwald, in which house, barn and stables are combined as in the Saxon farmhouse

Fig 16 shows a modern hygienic bed and Fig 17 the old fashioned alcove bed which was apparently devised to prevent access of fresh air to the sleeper

Fig 18 illustrates the comparative tensile strength of human bone and of oak A rod of bone having a cross section of one square millimeter will sustain a weight of 17 kilogrammes, while a similar oak rod will sustain only 10 kilogrammes By pressing the lever and raising the weight shown in Fig 19 which represents the effort made by the heart in each pulsation, the visitor can obtain a practical idea of the great force of the heart's beat

The effect of clothing in diminishing radiation of heat from the body is illustrated by Fig 20 When the temperature of the air is 50 deg F, the temperatures of the bare hand, the skin of the arm clad in a knit shirt and a woolen coat, and the other surfaces of the shirt sleeve and coat sleeve, are respectively 84.2, 89.6, 78.8 and 69.8 deg F. Hence the difference in temperature between the coat sleeve and the air is only 19 8 degrees, while the difference between the bare hand and the air is 34 8 degrees, and the radiation from the clothed arm is correspondingly less than that from the bare hand.

The heating and cooling effects of hats and caps are illustrated in Fig. 21 In the sun, with an external temperature of 96 8 deg F, the temperatures inside the hats are as follows No 1 yacht club cap, 98 6; No 2, Prussian helmet, 97.7, No. 3, English cap, 94 1; No 4, black derby hat, 92 3, No. 5, high silk hat, 89 6; No. 6, soft white felt hat, 86, No 7, light straw hat, 79 9, No 8, Panama hat, 77.9 deg F.

The First International Congress of Aerial Law

ON May 31st and June 1st and 2nd, the First International Congress of Aerial Law met in Paris under the auspices of the *Comité International Juridique de l'Aviation* The efforts of the committee are directed especially to the establishment of practical regulations for aerial traffic as such regulations shall become necessary The other objects of the committee are the collection and preservation, in a central place, of all interesting cases and documents relating to aerial law, the discussion and preparation of laws passed by parliaments and local authorities, and the imparting of information and advice to societies and individuals who may present questions concerning the legal aspects of aerial traffic In some cases the committee may assume the role of arbitrator in disputes

The committee has undertaken the preparation of an aerial code consisting of five sections (general public rights, private rights, police ordinances, custom house regulations and penal laws)

In a recent issue of the *Deutsche Zeitschrift fur Luftschiffahrt* the work of the International Committee is thus described by the head of the German delegation, Dr Alex Meyer

The separate chapters of the code tentatively adopted by the international committee are submitted to each national delegation and the result of the deliberations of each national delegation is communicated to the international delegate in Paris The diverse views thus collected from all the countries are discussed at the monthly sessions of the international committee, and form the basis of a provisional chapter, the definite form of which is established at the annual international congress

The first congress, just held, determined the method of voting, and drew up the first five chapters of the code, relating to general public rights It was decided that each country represented should have one vote The five chapters as adopted read substantially as follows

CHAPTER I GENERAL RULES OF AERIAL TRAFFIC

Article 1 Aerial traffic is free, with the reservation of the right of each State to make certain regulations for the space above its own territory, for the preservation of its own safety and the lives and property of its inhabitants

CHAPTER II NATIONALITY AND REGISTRATION OF AERIAL VESSELS

Art 2 Every aerial vessel must have a single nationality.

Art 3 The nationality of a vessel is determined by that of its owner When the owner is a company, the nationality of the vessel is that of the place where the company has its seat If a vessel belongs to several owners of different nationalities, its nationality is that of the owner who possesses a two-thirds interest in the vessel.

Art 4 Every vessel must bear an easily recognizable mark of nationality

Art 5. Every vessel must carry papers of identification containing all necessary information.

Art. 6. No owner of an aerial vessel may extend his flight beyond the limits of an aeronautic park unless the vessel has been registered in a list kept by the proper authorities. Each State shall make rules for registration in its own territory

Art 7 Every vessel must carry a mark indicating its place of registry

Art 8 The registration list shall be published.

CHAPTER III. LANDING.

Art. 9. Landing in open fields is permitted.

Art 10. It is forbidden to land in fortified places or within a radius established by the military authorities, or within towns and cities except in open spaces designated by the authorities.

Art. 11. The owner of the vessel shall be liable for all damage caused by landing, except in so far as such damage is caused by the fault of the party injured.

CHAPTER IV. JETTISON.

Art. 12 Jettison includes all voluntary dropping of objects from the vessel.

Art. 13. Except in cases of imminent peril it is forbidden to drop any object which can injure persons or property in any manner.

Art. 14. In case of injury so caused, the owner of the vessel shall be held liable.

CHAPTER V. WRECKED AND ABANDONED VESSELS.

Art. 15. Every person who finds a damaged or abandoned aerial vessel, or any part thereof, must notify the proper authorities.

Art. 16. The authorities so notified shall immediately take proper measures to preserve the wreck and restore it to its owner

Art 17. The owner may claim his property at any time within one year from the day of discovery and after he has paid the cost of salvage and preservation The owner is also required to pay to the finder a reward equal to 10 per cent of the value of the recovered vessel, after all costs have been paid.

Astronomical Notes for August

By Rev. Rudd W. Roberts

THE summer is the best season of the year for observing and studying the heavens. It is warm and the open air invites us all. It is especially favorable for the use of a telescope, for the "seeing" is much superior at this time. An instrument is worth one twice its size used in the winter season For these reasons we give below some notes with the hope that they will guide those interested in the study of the heavens

The Asteroids.

During the month of August Ceres, Juno, Pallas and Vesta may all be seen. As will be seen from the ephemeris given below Ceres passes just to the north of Eta Geminorum (R. A 6 hr., 9 min.; Dec north 22 degrees and 32 min.), about midnight on the 4th. It will lie about half a degree to the north of this star at this time. About noon of the 9th it will be directly north of Mu Geminorum—about half a degree above it. The R A. of this star is 6 hr. 17 min and its Dec. is N. 22 degrees and 33 min

Pallas is in the constellation Eridanus and toward the close of the month passes near the star 39 in this constellation Juno although of nearly the eleventh magnitude should be seen in a fair sized telescope on the 20th when it is about a half degree above Zeta Virginis The R. A. of this star is 13 hr. 39 min., and its Dec is south, 8 min Vesta is constantly growing brighter during August and at its beginning is near Delta Geminorum, and for a short time traces very closely the path of Neptune for the early spring. We give below the ephemeris for these asteroids:

CERES.

Mag	Date	Right Ascension	Declination.
8 71	Aug 4	6 hr 8 3 min.	N 23 deg 3 min.
	Aug 12	6 22 0	23 14
	Aug 20	6 35 4	23 21
8.53	Aug 28	6 48 5	23 26

PALLAS.

8.74	Aug 4	3 hr 25.9 min	S. 2 deg 28 min
	Aug 12	3 35.8	3 40
	Aug 20	3 45 0	5 5
8 39	Aug 28	3 53.5	6 44

JUNO

10 74	Aug 4	13 hr. 14.2 min.	N. 0 deg 59 min.
	Aug 12	13 21 6	0 10
	Aug 20	13 29 5	S. 0 41
10.94	Aug. 28	13 37 8	1 33

VESTA

8.65	Aug 4	7 hr 17.5 min	N. 21 deg 50 min.
	Aug 12	7 32.2	21 30
	Aug 20	7 46 6	21 6
8.53	Aug. 28	8 0.8	20 39

Occultation of Stars by the Moon.

In our article of April 1st attention was called to the pleasing experience of watching a star suddenly dart behind the moon during an occultation. Below is given the Washington Mean Time of Immersion and Emersion of three stars which may be watched during August.

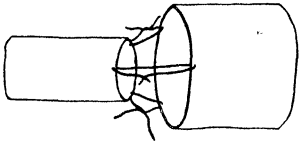
Date.	Star's Name.	Time of Immersion. Hr.	Min.	Time of Emersion. Hr	Min.	Mag.
August 5th. . .	10 G. Sagittarii	10	17 P. M.	11	5 P. M.	5.7
August 8th . . .	25 Capricorni	8	21 P. M.	9	39 P. M.	6.0
August 10th. . . .	27 Capricorni	2	6 A. M.	3	15 A. M.	5.7

Planetary Details to be Observed.

On August 28th the moon passes very close to Jupiter. Mercury is at its greatest elongation east of the Sun on the morning of the 12th and should be watched for about this time of the month, in the evening sky. It represents a crescent of about the same as the quarter moon at this time. Venus is at its greatest brilliancy on the 10th and is at this time half way been a quarter-moon crescent and a new-moon crescent.

The New Era of Blood-transfusion

A Triumph of Surgical Skill



By Genevieve Grandcourt

IT is not seldom that we read newspaper accounts like the following, which appeared early in the year:

"Philadelphia, Feb. 20th.—With a subject selected from the score or more volunteers who had offered their blood in response to a want advertisement that appeared in a newspaper here this morning, a remarkable transfusion operation was performed to-night in the Polyclinic Hospital The patient was David Poloco, a poor tailor suffering from internal hemorrhages, whose family had already given all the blood their physicians would allow, and had advertised to give their savings for a volunteer in a last effort to save the life of their relative.

"The subject, who hid his identity under the name of 'Smith,' was a powerful looking man about 26 years old who came to the hospital in a taxicab and is said to be a member of a prominent family in this city

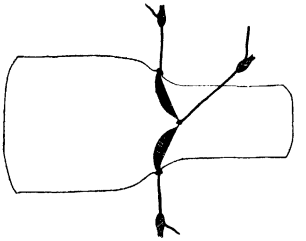
"The transfusion was permitted to continue for thirty minutes, when the white face of the patient had assumed a rosy hue, while the face of the subject, which at the beginning of the operation was ruddy, had become almost deadly white An examination of the blood of the two men at the close of the operation showed that the coloring matter in Poloco's blood had risen from 18 to 47 per cent, while that of the subject had decreased from 85 to 60 per cent"

First stitches or stay-sutures.

CARREL METHOD

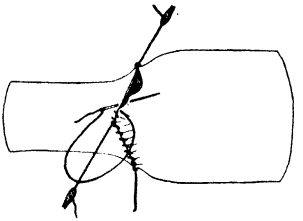
Dr. Crile of Cleveland, who more than anyone else has developed transfusion (the name of experimenters in the past two hundred years is legion), says that he meets with the warmest enthusiasm in asking relatives to make this sacrifice, while Dr Carrel describes the moral exaltation of a young man who gave his blood to his aged father. It would thus seem that the victory registered over the material is as blood-stirring as the surgical triumph of transfusion itself.

Not that the operation is any longer dangerous Professional donors of blood have been known to return to hospitals two and three times to repeat the experience; they are often in condition to work the next day. The ordeal is painless About half an hour beforehand, each patient is given a hypodermic injection of morphine Local anaesthesia is used, a small cut being made over the vessels



Reducing the surgical history of transfusion into its elements, it began with one Frenchman and was concluded by another; one in the 17th the other in the 20th century—Jean Denys, who performed the first real operation of the kind, and Alexis Carrel, who found the way to suture the ends of severed blood vessels

Denys, through animal-experimentation, arrived at conclusions as to choice of blood-vessels in transfusion which are held valid to-day. He showed that the artery (as carrier for the quick-flowing red blood) should furnish the supply, and the vein of the sick man should be selected to receive it, as affording the most direct route back to the right heart and the lungs where the blood becomes re-vitalized Artery and vein he connected with glass-tube

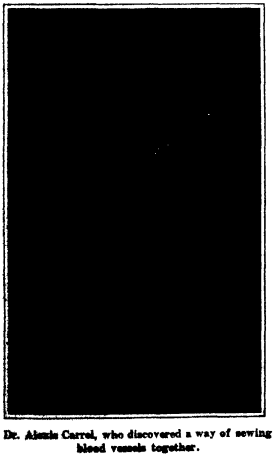


He was not sustained by the professional opinion of his time, partly because Harvey's discovery of the circulation, though forty years old, was still ridiculed in Paris, but also in view of the demonstrated negligible quantity of blood capable of being transfused. It had been known for a long time that endothelium, lining arteries and veins (now known as the intima), has the property, practically peculiar to itself, that blood in contact with it does not clot, while, when brought into contact with any other substance, it soon coagulates and ceases to flow

Denys found that the amount of blood transfused varied according to the size of tube used, and also according to the different size of human and sub-human blood-vessels; though he knew there was no way of satisfactorily gaging the flow save by the pulse of the donor which during the operation must be transmitted from artery to vein. As little as four ounces had brought patients out of syncope, and failure in one case that had promised well, was found on post-mortem to be due to intestinal gangrene.

After initiating the work, he got into trouble In transfusing blood from the femoral artery of a calf into the veins of an insane man, he was twice successful; but the third trial, made at the insistence of the patient's wife, resulted fatally Denys was sus-

Tying of stay-sutures.

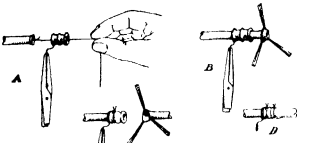


Final suture of artery and vein, showing over-and-over stitches completed between two of the stay-sutures.

CARREL METHOD

picious and wished to open the body The widow refused, saying he had "experimented" on her husband, and demanding a price for her silence The doctor's answer was a complaint to the authorities, and in the sequel the French government prohibited the practice

From this time until early in the 19th century, this operation was taken up, dropped and taken up at intervals until the method came into vogue of drawing blood from the subject, whipping out the clots



Dr. Alexis Carrel, who discovered a way of sewing blood vessels together.

(*defibrinating* it) and injecting it into the patient's veins

Against this method, the great French physiologist Magendie, gave early warning His experiments showed that in this way serious symptoms could be made to develop in perfectly healthy animals, and he suspected that the clotting took place now inside the body instead of out, producing paralysis and death During the Franco-German war, this method was tried on thirty-seven wounded soldiers with only thirteen successes

A few years later, science began taking those enormous strides which especially in physiology and bio chemistry have covered more ground than in all preceding history It was learned that that microscopic body, the white corpuscle, was back of the blood clot, that when the ends of blood-vessels were cut, it began

From Crile's "Hemorrhage and Transfusion" Appleton & Co

A Vein being drawn through ring *B* Cuffing vein over ring, showing hemostats *C* Vein tied in groove next handle of ring, artery in position to be drawn over vein *D* Complete anastomosis of artery and vein

CRILE METHOD

to manufacture fibrin ferment Hence, defibrinating the blood did not solve the problem as only the solid part of the clot was whipped out and the white corpuscle's fibrin ferment remained in the blood And it was only when this clotting inside the blood vessels did not take place in a *vital* organ that Magendie's prognosis was not realized

Thus the only solution was to join the ends of the blood vessels together so that, as regarded the circulation, they should become one But stitches seemed out of the question, since, being foreign bodies, they were as objectionable to the white corpuscle as tubes of glass or paraffine Yet, if hazardous operations of various kinds ever were to be made safe to be able to join blood vessels end to end was imperative

Payr answered this call with a magnesium-tube, but the technique was undeveloped and proved clumsy Meantime, Carrel was investigating with the blood-vessels of dead human bodies, he applied his technique to living animals, and it worked He had found the way to do that which everyone had said could not be done, to sew the blood vessels together without clotting or leakage

The principle of the Carrel method consists in "everting" (turning out) the cut lips of the vessels in such a way that when the openings of the two are brought together, their linings touch Needle and thread is then drawn through *sterilized vaseline*, passed through the outer and upper edge of the artery in its entire thickness, and brought out through the inner and upper surface of the vein Two similar stitches are made in the blood vessels (see diagram), in all instances leaving about four inches of thread uncut after tying, to serve as a handle for the assistant surgeon to tilt the blood-vessels in order to join them end to end, as shown in the accompanying illustration

Carrel's discovery was hailed with thanksgiving and he made an early application of it in transfusion by saving the life of a four day-old baby, this as recently as 1908

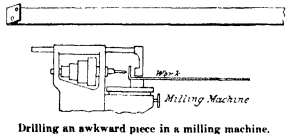
Dynamics.

Before Carrel's success, Crile was studying to develop transfusion along mechanical lines He used Payr's tube, discarded it for Carrel's stitches, and then deciding that the less skillful surgeon needed an easier method, developed the Payr tube The instrument he has evolved is a cannula or ring-with-handle, and is so tiny as scarcely to slip over the point of a pencil

The Crile method is to draw the vein *through* the ring and cuff its edge back on the ring, there it is

(Continued on page 129)

HANDY MAN'S WORKSHOP



[The Editor of Handy Man's Workshop will be glad to receive any suggestions for this department and will pay for them, promptly, if available.]

Drilling an Awkward Piece

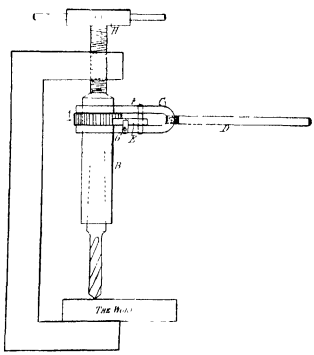
By G. H. Ander

THE following may be worth while to many, as it was to those it concerned when it happened

I was working in a railroad repair shop one day when I observed two machinists working a ratchet drill in order to make holes in a piece of iron about 12 feet long with one end bent up about 8 inches. The holes were being made in the short part (see illustration). The shape of the iron to be bored or

Drilling an awkward piece in a milling machine.

drilled prevented it from being done in a drill-press or lathe.



The men had the iron and ratchet drill with its holder clamped to an iron table and were working hard for a considerably long time to make the holes.

I asked the foreman if there were many jobs like that in the place. "Yes" he said "we have had to make quite a number of them in the last three years, and we will have many more." Then I said: "I suggest that you drill those holes by using that milling machine" (pointing to one which was used very seldom). "Well well," he exclaimed, "I never thought of that before, and neither did the machinists who were told to perform the job." After that the holes were always drilled in the milling machine by one man and naturally in very much shorter time than it used to require two men with the ratchet drill.

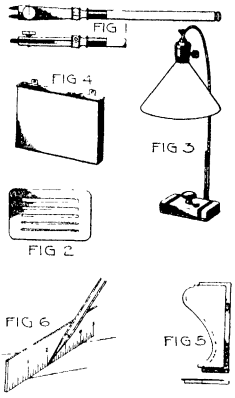
How to Make a Ratchet-drill

THE ratchet drill here illustrated will be found extremely handy around the house for quick repairs. Take an old milling machine cutter that has seen its best days and anneal it. This will make as good a ratchet wheel as you want.

A ratchet wheel, *A*, should be keyed on the drill carrier or spindle *B*. Then bend a piece of strap iron

A home-made ratchet drill.

to a U shape as shown at *C*, and drill a hole in the end of the U-shape iron, so it will be a neat sliding fit over the spindle *B*. A hole must also be drilled in the outer end of strap iron, so that a piece of round iron or pipe can be screwed in position so as to act as a handle shown at *D*. A dog, *E*, is pivoted upon a pin, *F*, and a spring, *G*, holds the dog against the ratchet wheel, *A*. While drilling a hole the drill is fed into the work by means of a feed screw, *H*, which is provided with four pins as shown in the head of the screw, thus making it easy to feed the drill into the work. The feed screw, *H*, has a female center which fits over the center of spindle, *B*. The ratchet held in this way will be held very rigid. The spindle is made so it will take any size of drill having a No. 1 shank.



Drafting Room Kinks

By John D. Adams

ON drawings where the lettering is considerably scattered and some degree of uniformity is desired, it is quite essential that some rapid means be provided for drawing the pairs of parallel guide lines. Measuring is altogether too slow. In most drafting rooms will be found one of those rather large, obsolete, right-line pens. Cut off the points, as shown in Fig. 1. Insert two chisel-pointed leads, and tighten the screw. When adjusting the distance between the leads it is only necessary to partially loosen the screw, after which the leads may be pushed in or out. This instrument is very rapid, and requires infrequent sharpening.

Fig. 2 illustrates another method of accomplishing the same end. A piece of transparent celluloid is provided with a series of slots of different widths. Although this little device is common, it is not to be found in any of the catalogues. It is superior to Fig. 1 where the lettering must not only be uniform, but of certain standard heights.

The writer has used several excellent forms of

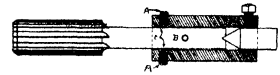
Drafting room kinks.

lighting fixtures for the drafting table, but none that gave more satisfaction than the little light shown in Fig. 3, which was improvised in the course of a half hour from a piece of heavy copper wire and a paper weight. On one end of the copper wire a hook is formed. The wire then curves downward toward the base, where it is bent into a rectangle the size of the paper weight. The extra length of wire is then carried upward and neatly bound to the vertical section. Two pieces of cord serve to connect the wire securely to the paper weight, and also to keep the base from scratching the table top. The electric cord in leaving the socket is fastened to the hook, from which it may be run directly to the outlet, or else down the curved copper standard and once around the knob on the paper weight. The latter is the better method. A shade of Bristol board answers every purpose, and the resulting lightness of this feature, as well as the upper works in general, renders the lamp very stable and easy to shift.

For those who have too little office space to accommodate the usual horizontal blueprint tank and yet find it necessary to make a few prints occasionally, the vertical tank shown in Fig. 4 will be convenient. This need be only an inch or two in thickness, so that the space it occupies is negligible. One or more wires running longitudinally across the top will serve to hold the prints while washing. The writer has seen a print two by three feet washed in one of the stock metal tubes used for keeping blueprint paper. These tubes are about two and a half inches in diameter and have screw tops.

In Fig. 5 is a suggestion to draftsmen who have to use special curves very frequently. A piece of transparent celluloid, which may be obtained at most stationers, is placed over the pencil outline of the desired curve, which is then marked off. The curve is then cut out with the shears and smoothed up with file or sandpaper. A piece of cardboard will serve to keep the celluloid far enough away from the paper to permit the use of the ruling pen.

There are comparatively few draftsmen who fully appreciate the possibilities of the ordinary flat machinist scale. With a little practice this form of scale may be readily handled on edge in which position spacing may be done with almost mathematical accuracy, as a sharp pencil point fits into the small grooves that mark the distances on the scale. In fact, there is probably no other method by which a point can be placed accurately and quickly.



Supposing that in Fig. 6 it is desired to subdivide the space between the two parallel lines into thirteen equal parts. Simply place the scale at a suitable angle to the parallel lines so that thirteen equal divisions—in this case quarters—exactly reach from one line to the other. Run the pencil point down each quarter mark, and the spacing is done.

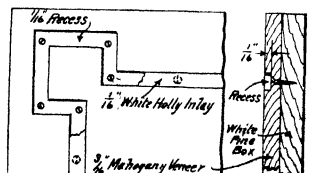
Floating Reamer for Lathe

By H. D. Chapman

THE accompanying engraving shows how a floating reamer can be made and the way it is used.

For very accurate work the floating reamer has come to be the standard. This style of reamer the writer has used very successfully on a lathe.

Floating reamer for lathe.



The reamer is held in a holder as shown, the holder is bored about 1/64-inch larger than the body of reamer. This is done so as to allow the reamer free movement. The reamer is held as shown against a center at the back and it has a pin through it at *B*, which prevents the reamer from turning. The hole that is drilled through the holder should provide about 1/64-inch clearance, so that the reamer can find its center while in use. There are four springs shown at *C* which are used to adjust the reamer into alinement with the work. These springs are held in position by means of set screws *A*. This reamer has now been in service for about two years and is used for reaming draw tubes for telescopes.

A Novel Method for Attaching Veneer

By R. C. D.

SOME time ago the writer had occasion to veneer a large box with mahogany. Not having the necessary facilities for glueing the veneer and clamping it in place until it was thoroughly set, as is the usual method, he proceeded to attach it as shown in the accompanying illustration. It is a simple method, and one which gave excellent results.

The mahogany was about 3/16 inch thick, and it was to be inlaid with 1/16 inch white holly. The recesses for the inlay were first cut out. The mahog-

Method of attaching veneer.

any was then placed in position on the box which was of white pine, and was firmly attached to it by means of screws which were placed at various intervals in the recesses. The heads of the screws were countersunk into the bottom of the recesses as shown. The white holly was then laid in the recesses and secured in place with glue and thus all traces of how the veneer was held in place were completely hidden.

This is a trick worth knowing and it may come in handy for a number of our craftsmen friends who have like work to do.

The Inventor's Department

Simple Patent Law; Patent Office News; Inventions New and Interesting

The British Inventor: His Decadence and the Remedy.

IN an article published in the London *Engineer* Mr. W. O. Hornsall analyses the reasons why England has fallen behind other nations as regards the evolution of useful inventions.

In its editorial columns, the *Engineer* firmly declines to agree with Mr. Hornsall in the assumption that British invention is at all in a backward state, and cites the British man-of-war. "From beginning to end," states our contemporary, "she is the product of British imagination, British thought and British skill, and it will not be denied that she contains a collection of inventions for which it would be hard to find an equal outside of an international exhibition. We are not going to attempt the impossible task of separating the details of her contents according to the nationality of thought which first inspired them, though, if we did so, the preponderance of British inventiveness would be enormous, but we shall content ourselves by pointing out that nearly every one of the million details which may be found within her walls has been thought out in British drawing-offices."

Mr Hornsall states that the attitude of the British manufacturer toward new inventions is one of apathy, coupled with extreme skepticism. The manufacturer can be induced to take up a new patent only under an agreement giving him the lion's share of the profit, while the inventor is saddled with all the risks.

"The majority of ideas cannot be put into workable shape without patient and often costly experimenting, hence an inventor with out means of his own must apply either to a capitalist or a manufacturer for assistance. The former is very chary of risking his money in such ventures, in view of the attitude of the manufacturer indicated above, and the latter, if he can be persuaded to take any interest at all in the idea stage, will suggest employing the inventor under an agreement by which he surrenders all claims to any improvements resulting from his efforts. This state of things compares unfavorably with the attitude of manufacturers towards inventions in certain other countries who now give us the lead in this line.

"In view of the epoch making inventions brought out by British enterprise during the last century, it is difficult to believe that our inventors are suffering from any lack of originality, this view being further supported by the large and increasing number of applications for letters patent. Such being the case we are driven to the conclusion that the chances of a reward, which were good enough to attract the best brains in the country thirty to fifty years ago, have now become too remote to act in this way, with the result that our manufactures have been reduced to copying the inventions of other nations. There is little room for doubt that the position is mainly governed by the attitude of the manufacturer both as regards the independent inventor and his own employees.

"It is not intended to suggest that the majority of the British firms make no recompense whatever to workpeople who bring forward valuable inventions, but the reward is generally in the form of a small increase in salary, which may, and often does, end after a short period owing to a revision of the staff appointments. Only a very few manufacturers employ experimenters whose whole duty consists in developing new products, and the chances of a small increase of salary for an uncertain period are not sufficiently attractive to induce inventive efforts in those who have been engaged for other duties; hence, if a good idea is thought of, the experienced assistant will keep it to himself until he secures a new appointment, when protection can be obtained between engagements.

"It is difficult to understand what objection there can be to paying a small royalty to a workman. It would have to be paid to an independent inventor, and, after all, the firm is placed under no permanent obligation, as the royalty ceases with the manufacture; moreover, much better terms can be arranged than would be practicable in taking up the invention of an outsider. It is only fair to state that certain enlightened firms have been very liberal with members of their staff who have brought out new inventions and such concerns have greatly benefited by this procedure, but the general rule is to give no royalties to workmen, whether engaged for experimental work or other duties."

Mr Hornsall believes that one reason for the lack of English success in the direction of new inventions is the neglect of experimental and research work by manufacturing concerns. This plan is in marked contrast to the methods pursued in Germany, where almost every large works has a number of men continually engaged in experimental and research work, no attempt being made to economize in this department, even during periods of depression.

"Often the cost of manufacture is entirely ignored, but it is obviously useless to protect a device which cannot be made for a price at which it is likely to sell.

"It would appear that an inventor if he is not an expert in the industry to which his idea applies, would often be well advised in consulting some one whose knowledge and experience would enable him to say whether the invention was likely to prove successful, and this course should be pursued before any money is spent upon taking out a patent. It will no doubt be contended that by such procedure the inventor risks having his idea taken from him for the use of some one else. If, however, care is exercised in the selection of an expert, this risk should be infinitesimal, and in the case of a useless invention the outlay upon patent fees, experiments, models and attempts to sell, are saved.

"Then again, expert knowledge is necessary for the perfecting of an invention before any attempt is made to place it upon the market, and if the inventor does not possess such knowledge he should certainly seek assistance.

"Many good inventions have failed because they have been offered to manufacturers in an imperfect state, backed up by inefficient designs and carelessly constructed models. The drawings of the invention, and the workmanship of the model, are most important when it is desired to sell a patent. A number of mechanical inventions have made a market for themselves without possession any merit whatever, excepting they have been well designed and made while others, with novel and useful features of considerable value, have failed to receive recognition owing to the careless way in which they have been put forward."

Notes for Inventors

A New Way of Hanging Clothes.—A city dweller once built his garage on the back of his home lot, shortening his yard and causing the women folks to complain of lacking space to hang the family wash. "Oh!" he said, "I'll fix that." He ran two small iron pipes, which had formed parts of an awning frame, lengthwise along and supported from the side fences by brackets which spaced the piping away from the fences. Then the clothes line was laced from side to side of the yard around the opposite pipes. When a row of wash was hung, it could be pushed along close to the preceding row, so that the capacity of the yard was equal to, if not greater than, that of the entire original yard when hung in the usual manner.

A Perpetual Motion Inventor and His Practical Suggestion.—Misdirected effort is frequently found in the pursuit of inventions, and we read of the death a short while ago of a Baltimore inventor eighty-eight years of age who is said to have spent fifty-five years of his long life seeking perpetual motion. At the same time we read of the old man's evidencing his natural and developed inventive ability by suggesting to a relative, as a wedding present, a reaping invention which is reported to have realized one million dollars or more. If this be true, his inventive talents can hardly be said to have been given him in vain.

A Parsons Turbine Gearing.—In a patent, No. 997,635, Charles Algernon Parsons of Newcastle upon Tyne, England, provides for the running of turbine elements at their most economical speed independently of the speed of the propeller shafts. He does this by combining, in the turbine installation, one or more propeller shafts with a plurality of other shafts and gearing between said shafts, together with turbine elements some of which are reversing turbine elements distributed over all the shafts, all arranged to secure the economical speed of the turbine elements.

Recent Patents for Treatment of Refractory Material. The treatment of refractory material is involved in five patents, Nos. 997,879 to 997,883, issued to the General Electric Company, assignee of Ezechiel Weintraub of Lynn, Mass., and Schenectady. The same company is assignee of patent No. 997,940, to Elihu Thomson of Swampscott, Mass., for a method of generating high temperatures, in which the vapor is generated in a conduit of relatively unrestricted bore by heating the conduit externally, accompanied by other steps in the process.

An Observation Car.—An observation car in which seats are arranged sloping upwardly from both ends of the car to a central level portion is shown in a patent, No. 997,704, to Richard M. Rodden of Montreal, Canada.

Cleaning Glass Dry.—In a patent, No. 997,447, Samuel Grimson of New York city provides a dry cleaner for glass, in which a cleansing surface of tripoli powder is held to a suitable backing by a minute coating of vaseline, which will hold the tripoli to the backing without passing through the powder.

A Parachute for Aeroplanes.—A safety attachment for aeroplanes has been patented, No. 997,454, by Grover C. Youngreen of Los Angeles, Cal., and includes a sheet of fabric which may be folded in triangular form into a vertical plane to promote lateral stability of the aeroplane, or may be folded into a horizontal plane to act as a parachute.

Another Marconi Patent.—Guglielmo Marconi of London, assignor to the Marconi Wireless Telegraph Company of America, New York, N. Y., has secured patent No. 997,808 for a transmitting apparatus for wireless telegraphy. Any reference to the transmitter is necessarily technical, but the improvement includes a battery of low resistance with moving terminals arranged so that a gap is left between them, together with pieces to bridge the gap, which bridging pieces are moved, in operation, rapidly past the gap.

A Cup Packer for Wells.—A cup packer for wells, in which a cup formed of material which softens under the influence of liquid, is combined with a spring of insufficient strength to expand the cup when dry, but can expand the cup when softened by the liquid, is presented in a patent, No. 997,721, to Charles A. Wartz of Rousseville, Pa.

A Group of Safe and Vault Patents.—Twenty-five patents, Nos. 997,771 to 997,795, inclusive, have recently issued to Taylor Iron and Steel Company, High Bridge, N. J., as assignee of Samuel W. Fish of Plainfield, N. J., for safes or vaults, safe or vault doors, safe or vault bodies, safe or vault door holding means, locking mechanism for safes or vaults, and safe or vault door holding or locking means.

S. P. C. A. Horseshoe Prize.—Early in the year the American Society for the Prevention of Cruelty to Animals instituted a prize competition for a shoe which would prevent horses from slipping. The competition was to close on June 1st, 1911. We are informed by the general manager of the society that it is unlikely that any experiments will be made or decisions arrived at until the advent of winter, as the object is to find a shoe or device that will prevent horses from slipping on icy pavements.

The Death of Samuel T. Fisher.—Mr. Samuel T. Fisher, who was Assistant Commissioner of Patents during the Cleveland administration, died in Washington, Saturday, July 22nd, 1911. Mr. Fisher was a graduate of Harvard, subsequently taking a special course at the Massachusetts Institute of Technology to fit himself for work as a surveyor, which he followed in the United States service in Colorado and then returned to Massachusetts, studied law and accepted a position as assistant examiner in the United States Patent Office rising to the assistant commissionership. Later he resigned to enter the practice of patent law which he followed with signal success up to a few months ago, when he was stricken with what proved to be his last illness.

A Waterproof Cellar.—In some sections ordinary cellars are impracticable, and James William Lane of Atlantic City, N. J., provides in a patent, No. 997,835, a waterproof cellar having a waterproof concrete floor and walls of considerable thickness with a vertical standpipe centrally on the floor and extending above the normal height of the water, in the surrounding sand, the standpipe having a filter and the standpipe being open at both ends, so that water may rise and fall freely therein.

A New Two-cycle Engine.—Charles Francis Jenkins of Washington, D. C., a well-known inventor especially in the moving picture apparatus art has recently obtained a patent No. 997,195 for a two-cycle gas engine including a longitudinal passage outside of the cylinder and within the water space of the same, one end of the passage being in open communication with the upper end of the cylinder while its lower end, in which a spark plug is located, is opened and closed by the reciprocation of the piston.

Doping Gasoline.—A real estate agent of our acquaintance uses a light runabout machine, and says he can get about eighteen to twenty-one miles out of a gallon of gasoline, but that he finds if he puts an ounce of laudanum to each five gallons of gasoline, he will increase the mileage per gallon from twenty to twenty-five per cent. Whether this is so or not—and no reason is seen why any such effect should result from the use of laudanum—it calls to our attention the use of additions to the explosive fluids for increasing their efficiency. The use of nitro compounds, such, for instance, as picric acid have been suggested. As early as 1903 Le Marc, an engineer of Brussels Belgium obtained an English patent No. 3,623 for an invention whose object was to increase the number of available calories for a given weight of fuel. He proposed an explosive fluid mixture combining 30 per cent of nitro-benzine with 70 per cent of alcohol. The fuel carried by motor cars should of course be as rich as possible in calorific energy, and a compound that can be provided for addition to the fuel charge of an automobile or motor boat should find a ready sale if it can increase the mileage per gallon or can reduce the expense without adding to the dangers of operation. While some think the development of aeronautics will be greatly affected by improvements in the fuel products, others look for material improvements in the motors, and we have seen no less an authority than Hiram Percy Maxim quoted as prophesying that "in a few years we may get a thousand horse-power within the weight we now use for ten."

RECENTLY PATENTED INVENTIONS.

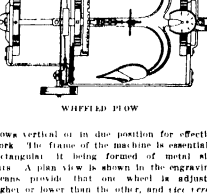
These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Pertaining to Apparel.

CONVERTIBLE COLLAR.—A. M. HAZEN, New York, N. Y. This garment improvement relates particularly to a reversible collar, which may be changed from a perfect normal to a perfect military collar. The invention provides a collar to which the outer or normally visible surface of the normal collar is perfectly protected from being soiled when reversed to form the military collar.

HAT GUARD.—A. F. WILLEMAN, 70 Goldhurst Terrace, Hampstead, London, N. W., England. This invention refers to what may be termed safety pin hook and eye fastenings; that is, fastenings which are provided with a pin serving in lieu of sewing, for securing the fastening to articles of ladies' attire. The improvement consists more particularly in the method of securing a pin to each element of a fastening made from stamped up metal.

Electrical Devices.



FUSE SWITCH.—A. L. WEEKES, Harpendale, Herts, England. This invention relates to fuse switches, that is, switches in which the current is caused to pass over fuses forming part thereof. Current is cut off by way of one contact spring switch blade, spring clip and fuse to the other spring clip switch blade and contact. The arrangement of the fuse member at right angles to the switch arm so that two ends of the fuse bridge the switch blades move simultaneously away from the main contacts and in a parallel way is an important feature. The blades formed as spring members enable solid main contacts to be used.

TIMER.—G. T. BROWN, New York, N. Y. This timer is for use in controlling the closing of a plurality of electric circuits in succession and relates more particularly to the type of timer commonly employed with the electric ignition system of multiple cylinder internal combustion engines. The timer is formed so that the length of time during which the contact is made will be sustained fully uniform irrespective of the speed of the engine.

Of Interest to Farmers.

COTTON CLEANER.—A. L. BREESE, Jennings, Okla. Among the principal objects in view in this case are: To provide a mechanism for cleaning cotton by pneumatically eliminating the dust and dirt therefrom; to provide means for controlling the operation of the cleaner and to provide a cleaner which is continuous in its operation.

WHEELED PLOW.—JOHN N. TINDEL, Rupert, Idaho. This invention is an improvement in reversible wheeled plows in which the frame to which the plow bodies are attached is adapted for adjustment relative to the main frame and the wheels, as required for plowing deeper or shallower and for holding the

WHEELED PLOW.

plows vertical or in due position for effective work. The frame of the machine is essentially rectangular, it being formed of metal side bars. A plan view is shown in the engraving. Means provide that one wheel is adjusted higher or lower than the other, and vice versa, whereby the level of the plow frame is preserved while one wheel runs in the furrow and the other on the unbroken land.

ANCHOR FOR WIRE FENCES.—J. RINEHART, Vanatta, Ohio. In this patent the invention is an improvement in anchors, and is designed to hold down the wire of fences between the fence posts to prevent the wire from being raised by hogs. The invention further resides in a driving block for sinking the anchor in the ground, with the tie wire in place.

INCUBATOR LAMP CHIMNEY.—G. H. LEE, Omaha, Neb. Among the principal objects which the present invention has in view are: To provide a cover for a lamp chimney constructed to control the circulation of air in connection therewith to prevent heat loss by radiation, and to provide a cover for a lamp chimney so constructed as to extinguish the said lamp when same is caused to smoke to excess.

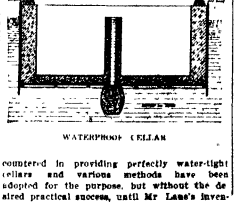
Of General Interest.

BOX.—W. W. BAIRD, Cleveland, Ohio. An object here is to provide a blank, which may be cut in one operation with very little waste and which may be quickly set up to form a box. Another object is to provide a box with no creases to weaken the walls of the box, the box being so constructed that when it is set up the side walls cannot become dislodged, except when desired.

AUTOMATIC VALVE CLOSURE FOR WATER COCKS OR FAUCETS.—V. L. GARCIA, Buenos Aires, Argentina. The present invention relates to an automatic valve closure for water cocks or faucets, adapted to be acted upon by the pressure of the water itself. The body of the faucet consists of two parts screwed together and between these is a pure rubber disk which serves both as a valve and a means for making a tight joint between the parts of the body. Pure rubber keeps its elastic qualities without alteration within the water, as it is the oxidizing effect of dry air which deteriorates and destroys the rubber.

DRYING METHOD.—K. RETSCHER, Bielefeld, Germany. The method consists in passing the goods in two sections in opposite directions through two currents of air, each current passing over the dried departing portion of one section, then over the heater and then over the wet portion of the other section, whereby the air currents receive the preliminary heat by contact with the dried goods and are then heated by the heater, and finally come in contact with the entering wet goods to quickly dry the same prior to the latter reaching the exit portion of the drying chamber.

CLIP ATTACHMENT FOR PAPER ROLLS.—W. H. HULL, G. L. CUTLER, and A. A. BAUMAN, Gregory, S. D. By means of the attachment the operator severs any required length of the paper from the roll is facilitated so that it may be performed in about half the time required with the old attachment. Such rapidity of action is due largely to the fact that the end of the paper strip is held separated from the roll proper so that it may be conveniently and quickly severed.



UMBRELLA CLOTH OR COVERING.—J. HYMAN, Shamarokck, N. Y. An umbrella covering made from the umbrella cloth is exceedingly serviceable and has high wearing quality, and arranged to properly shed the water, owing to the silk face formed by the silk weft threads extending outwardly to the selvage, which latter by its longitudinal ribs give a fine appearance to the umbrella.

PLATE METAL TUBING.—P. H. FURH, Kewaska, Wis. The invention provides a pliable covering material and a rigid body structure inclosed within the material and disposed to prevent the opening of the joint of the material, provides a sheet metal tube, the edges whereof are folded, and means whereby are provided with means for locking the joint to prevent the opening of the same and provides a locking member for unfolding and holding the edges of metal bent to form a tube said member being disposed within the tube.

SPARK ARRESTER.—W. T. DEPEW, St. Louis, Mich. Mr. Depew's invention is an attachment for locomotive smoke-stacks and the chimneys of stationary furnaces for the purpose of arresting sparks and cinders and preventing them to the fire-box. It is only necessary to modify the apparatus in respect to size and in some cases slightly in respect to form to adapt it to various uses.

RUG DISPLAYER.—W. J. SMITH, Tiffin, Ohio. The purpose here is to provide a device for holding rugs in such manner that without injury to the rugs, they may be presented to the inspection of the purchaser to the best advantage, and wherein the rug may be easily released from the holding means when released.

WATERPROOF CELLAR.—JAMES W. LANE, 2015 Baltic Avenue, Atlantic City, N. J. In some seashore cities and other locations where sandy soil is permeated with water to a short distance below the surface, especially in Atlantic City, N. J., much difficulty has been en-

WATERPROOF CELLAR.

countered in providing perfectly water-tight cellars and various methods have been adopted for the purpose, but without the desired practical success, until Mr. Lane's invention was put in use. In the accompanying illustration there is shown a vertical longitudinal section of a cellar constructed in accordance with the invention.

UMBRELLA OR PARASOL.—M. PRELL, New York, N. Y. In this patent, use is made of a stick, formed with telescopic sections, of which one is the handle section and contains a spring pressing the other or crown section, which latter carries the crown on which the ribs are pivoted, the runner being mounted to slide on the handle section, and being connected by braces with the ribs, the latter being connected by auxiliary braces with the handle section.

BOAT RELEASING HOOK.—J. JORDAN, Sydney, Nova Scotia, Canada. In this case the invention relates to a new and improved hook adapted to be used in supporting a life-boat or the like, which may be attached to the boat proper or to tackle, and which is adapted to automatically release the boat from the supporting members by the simple movement of a catch.

LIFE BELT.—F. JONATA, New York, N. Y. The invention relates generally to life belts and more particularly it involves an improved construction of simple form, the structure of which embodies the use of suitable material, such as canvas, having a plurality of ribs positioned at various points therein, one end of the belt being provided with a suitable valve whereby air may be emitted or exhausted from the belt.

EMBOSSING PRESS.—A. E. STIGBERG, New York, N. Y. The invention is an improvement in hand-operated presses, more especially for printing names and addresses on paper, and has in view a press in which the dies can be readily removed and replaced by other dies and conveniently and inexpensively procured. Means provide for the impression to be made at a considerable distance from the edge of the sheet.

WATCH FOB.—H. O. BECK, Atlanta, Ga. The object of this inventor is to provide a fob of flexible material having a pocket for containing a picture, or the like, wherein the picture is hidden from view, but readily accessible. The fob may be constructed of leather or other material, and may be stamped with suitable ornamentation. The fastener for the flaps is the usual glove fastener.

LOOSE LEAF BINDER.—C. F. MCBEE, Athens, Ohio. The improvement provides a binder more especially designed for use in railroad offices, manufacturing and commercial establishments and the like, and arranged for filing and subsequently binding loose leaves of tissue paper between two covers in an inexpensive manner without it being necessary to have holes previously punched in the papers.

HARROW.—L. O. EBERN, Calumet, Mich. In the present patent the invention has reference to harrows and it has for its purpose to provide means for rotating the shaft to which knives are secured from the axle on which the wheels are mounted, and also means for raising arms to which the shaft is journaled, the arms being pivoted to the axle.

Hardware and Tools.

NUT LOCK.—J. B. FUNKHOUSER, New Brighton, Pa. This invention is an improvement in that class of nut locks in which a washer is used in connection with a washer in such manner as to engage the side of a nut and thus prevent its rotation. The locking device is so constructed and applied as to connect with the washer and the nut as to lock both.

DIAL LEVEL.—J. O. ORTMAN, Hancock, Mich. An object of this inventor is to provide a folding level in which the usual tube of liquid having a bubble as an indicator is dispensed with, forming a stronger and more durable level and having an indicator that will respond more quickly to variations in level, and will show more clearly and closely the amount of variation.

SYSTEM OF LAYING OUT STAIR RAILS.—C. C. GRANT, Red Deer, Alberta, Canada.—This invention relates to systems for laying out stair rails and the like, for use by carpenters, builders and others, and relates more particularly to a system including in combination, means for holding the work, and a marker adapted to engage the work, and movable in a plurality of directions to permit the laying out upon the work of the outlines of the stair rail.

HINGE ADJUSTING DEVICE.—H. C. ERNICH, Washington, D. C. An object of this inventor is to provide means for accurately adjusting the hinge, so that a door in its closed position will be in exact alignment with the sides of the casing. The device can be applied to any type of double hinge with very little trouble, and by its means the door may be brought into position through the adjusting members at any time after it is once hung, and with little effort.

LOCK.—R. FEOLA, New York, N. Y. An object in this case is to provide a simple, inexpensive and durable lock, which serves the purposes of the ordinary padlock, which, when in position, prevents the staples or eye-bolts from being filed or cut, and which renders different other unauthorized methods of opening the lock.

WIRE TWISTING TOOL.—D. A. CLAWSON, Waynesville, Ill. This tool is more especially designed for use in building wire fences, and arranged to permit twisting the vertical wire stays in between the line wires of the fence, twisting the ends of the wire stays a number of times and leaving the top and bottom line wires without requiring rotating the handle of the tool around the wire, and allowing placing of the stay wires close together.

LATCH.—O. A. KLEIN and N. S. PIRSBALL, New York, N. Y. The latch is adapted as a fastening for clothing, straps and general usage. It consists of two members, one a pocket normally open at the front, with an engaging spring overhanging the entrance of the pocket having a shoulder, the pocket having rigid sides, bottom and top walls, and the other a head constructed to lift the spring in passing into the pocket, and provided with a shoulder for automatically engaging the shoulder of the spring when the head is seated in the pocket, and means are provided that present no projections on which clothing may be accidentally caught.

STRIKING LINE.—H. K. KISO, New York, N. Y. This invention comprehends a disk-like casing in which is revolubly mounted a drum and upon this latter the line is wound. The unwinding turns the drum in one direction, and it is retracted by a spring. The casing is provided with a sector-like opening, and fitting into this opening is a hollow door through which the line is drawn, and disposed within the door is the inking apparatus.

LAWN CLEANER.—C. H. MOSHER, Salisbury Mills, N. Y. The object here is to provide side members, to which are pivoted members carrying a shaft having tube teeth and a bar having hooks, the shaft being rotated by gearing connected by the wheels supporting the side members. The pivoted members are adjustable relatively to the side members, and means are provided for holding them in adjusted positions relatively thereto.

RAZOR SHARPENER.—D. C. WILLIAMS, Arlington, Mass. This sharpener renews the edge of razor blades, and particularly that type known as safety blades, and used in such safety razors as the "Gillette." It will automatically sharpen simultaneously a plurality of edges of a blade. The device will also alternately sharpen the opposite edges of a blade in a continuous manner.

SHAVING SET.—J. W. HAWKINS, Passaic, N. J. The set contains in very compact form one or more ordinary razors, a strop, brush and soap, the arrangement being such that the strop can be conveniently placed in a stretched position above the casing for containing the enumerated articles. For the purpose mentioned the casing is made in two parts hinged together at adjacent ends, and the strop is supported at its ends on brackets carried by the casing parts.

FIRE EXTINGUISHER.—W. S. KELLOGG and C. E. SCOTT, Elizabeth, N. J. The invention comprehends more particularly means for liberating the acid at a point some distance below the surface of the alkaline liquid, in order to insure thorough and quick admixture of the acid and the alkaline liquid. The operator may cause the extinguisher to send forth either a liquid or a gas, and to direct the same, upwardly or downwardly.

Heating and Lighting.

FEED WATER REGULATOR.—C. O. BERGMARK, Chicago, Ill. The object of the inventor is to provide a new and improved regulator for use on steam boilers to regulate the flow of the feed water automatically, with a view of maintaining the feed water at an approximately uniform level, and to allow of filling the boiler beyond the normal level whenever desired.

APPARATUS FOR BURNING HYDROCARBON FUELS.—B. L. WORTHEN, Tucson, Ariz. The more particular purpose in this instance is to introduce finely comminuted carbonaceous material into a pre-existing flame, and to supply air or its equivalent at the point of contact between the comminuted material and the flame, so as to insure perfect combustion, economy of materials, and a high degree of heat.

FUSE LIGHTER.—H. W. FULLER, Globe, Ariz. This device is for use in igniting a fuse or fuses under water. It is designed for use especially with those fuses that are designed to explode charges in running operations. Many times excavated portions are up with water, so that it is often hard to explode the charges since the ends of the fuses become wet and therefore do not ignite, even though the outside of the fuse is protected with a waterproof covering.

Household Utilities.

FOLDABLE BED BOLSTER.—F. HANSEN, and J. ADAMS, New York, N. Y. This bolster is sanitary, and is arranged to permit convenient and quick adjustment and to allow ready folding of the parts for cleaning or storing purposes. For this purpose use is made of a tubular fabric cover, stretched over bands adjustably held apart by a rod extending through the cover and seated in sockets surrounding in said bands.

ATTACHING DEVICE FOR CURTAIN STRETCHERS.—J. O. SOMMERFIELD, Chicago, Ill.

The invention has reference more particularly to a device which comprises a base adapted to be movably carried by a suitable part of the frame of the stretchers, an upwardly projecting holder adapted to engage the curtain or other article stretched upon the frame, and a guard adjacent to the holder.

PERCOLATOR.—J. J. O'MARA, New York, N. Y. This percolator comprises a main pot, a heating chamber having an opening within the pot, a percolating tube, a container for the coffee from which the infusion is to be made, and arranged to have the percolating tube discharge over the material therein, and a connection for removably associating the tube and the heating chamber, this connection forming a tortuous passage connecting the tube and the chamber with the main pot.

RECEPTACLE FOR CONDENSED MILK CANS.—W. L. KING, Pittsburg, Pa. The aim of this invention is to provide a receptacle in which may be disposed a can, a lid having an opening being provided for covering the receptacle and having a spout adapted to be disposed over the spout of the receptacle. Means provide for covering the space between the periphery of the condensed milk can and the inner wall of the receptacle, and for holding the lid in place.

WINDOW FASTENER.—G. W STEIN, Chicago, Ill. In the present patent the invention has reference to means for fastening windows by a locking mechanism, and an object is the provision of a fastening device to be used for holding one sash in a fixed position with relation to the other which may be readily adjusted to permit the free movement of either sash.

WINDOW VENTILATOR AND FLY ESCAPE.—G. W STEIN, Chicago, Ill. The ventilator may be brought into instant use at any time without the necessity of raising or lowering the window sash. It will permit a circulation of air therethrough, but at the same time prevent snow or rain from blowing in through the openings. It may be readily attached to any window.

Machines and Mechanical Devices.

CHOCKING MECHANISM FOR COMPRESSES.—W. HILL, Alexandria, La. The principal object which the present invention has in view is to provide an efficient and rapid means for the adjustment and operation the rapid acting platen of a compress, the means being adapted for arrangement relative to the said rapid acting platen in any position to which the same is adjusted.

MAGAZINE FOR TYPE SETTING MACHINES.—J. J. HUMMEL, Spokane, Wash. This invention provides a magazine for holding type in position for delivery to a type setting machine having a feeding attachment adapted to mechanically deliver the type to the machine; provides for the said type graduated to the thickness of type being handled; provides for attaching the magazine to the font frame of a type setting machine; and provides a magazine to be rapidly and readily placed in position for refilling.

OPERATING KEYBOARD FOR TYPE SETTING MACHINES.—J. J. HUMMEL, Spokane, Wash. This invention provides a mechanism for rapidly operating the keys of a keyboard to arrest the carriers in their flight and in a manner to provide against conflict in selection of the type; provides a locking mechanism whereby the mentioned conflict is avoided; provides a mechanism arranged to produce a necessary interval of time between operations of the keys in harmony with the operation of the above mentioned rotary track mechanism supporting the type carriers.

FLYING MACHINE.—O. A. FENN, New York, N. Y. This invention is of the aeroplane type. An object is to provide a machine with a plurality of supporting planes, offset from one another out of vertical—alignment. Means provide for directing the vertical travel of the machine, and a universal rudder for further controlling the direction of travel of the machine. Supporting planes are provided capable of being distorted into parachute form.

POST MOLDING MACHINE.—A. W. SWOOKEN, Lonidas, Mich. The object here is to provide a machine for molding fence posts and the like, preferably of concrete, and adapted to mold posts of various shapes, depending entirely upon the form of mold used. The invention comprehends among its features, a self-brought tamping plunger for suitably tamping the concrete in the mold and pressing it into a shape similar to the form of the mold.

COMBINED ELEVATING AND FRUIT CLEANING MACHINE.—A. J. NYE, St. Petersburg, Fla. An object of this inventor is to provide a device by which fruit such as oranges, grapefruit, lemons, etc., may be thoroughly cleaned from scale, dirt or other impurities while being elevated from a lower to a higher floor. The fruit is held positively in position while being cleaned by a series of spring actuated brushes which conform to the contour of the fruit.

VALVES.—F. J. MEYER, Yonkers, N. Y. The object of Mr. Meyer's invention is to provide a combined improved valve for use with high or low pressure steam supply, and arranged to insure long life of the valve, to prolong the period of repairing or rewashering the valves, and to prevent waste of water by leakage.

TRIPLET BUCKET LADDER DREDGE.—M. S. GODIT, West Wareham, Mass. This invention pertains to a dredge of the endless bucket type, in which a plurality of individual bucket ladders are provided. An object is to provide a dredge with a plurality of ladders having endless bucket systems thereon, one of which operates in advance of the others in such manner that a more efficient operation of the device is obtained.

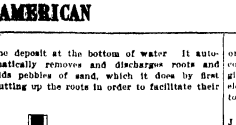
NUTCRACKING MACHINE.—B. W. ELDER, San Antonio, Texas. The invention refers more particularly to a machine which comprises a pair of movable members for actuating the same, and a cutter, the members having means for holding between them a nut, and serving to carry the same into engagement with and past the cutter to effect severing of the shell from the nut. Mr Elder has invented another nut cracking machine for cracking shells of different kinds of nuts, and it refers more particularly to a machine which comprises a pair of relatively movable cutter heads each having a cutter, and means for limiting the penetration of the cutters to prevent injury to the kernels of the nuts.

SOUND REPRODUCER AND RECORDER.—W. A. CHAPMAN, Smithville, Ark. The invention is particularly useful in connection with talking machines employing disk or other types of records upon which sounds are recorded in the form of grooves, and in which diaphragms are used to reproduce the sounds from the grooves, or to form the grooves upon blank records.

STRAIGHTENING MACHINE.—J. S. BACHMAN and C. E. MCLIN, Rome, Ga. The object of this invention is the provision of a machine for straightening previously used bale ties and for removing lint, jute or other extraneous matter from the straightened tie which extraneous matter may adhere to the tie from previous use.

APPARATUS FOR BENDING PRINTERS' RULES.—J. A. RICHARDS, Albion, Mich. This invention is an improvement in hand-operated apparatus employed for bending printers' rules and other thin metal bars used for various other purposes, and it is particularly an improvement upon the apparatus forming the subject of Patent No. 707,744. When this machine is made of large size it may be successfully used for bending much thicker bars or rods used for various other purposes.

AUTOMATIC CLOTH MEASURING AND PRICE CALCULATING MACHINE.—R. H. SHEPPE, Big Stone Gap, H. H. EZELL, Duffield, and C. D. ALLEN, Meadowview, Va. This device measures the number of yards of cloth sold, and at the same time calculates the total cost of the same. The invention provides a device in which any quantity of cloth, within reasonable limits, can be automatically registered, and the price thereof simultaneously exposed to view, with means for automatically returning the device to its original position.



COMBINED STUMP PULLER AND STUMP PILER.—I. L. MITCHELL, Cedar Rapids, Iowa. Stump pullers of a certain type are provided with a rotary drum on which is wound a chain or rope that in practice is extended and attached to stumps or trees to be removed. The inventor has made improvements in such pullers and has combined therewith an attachment for swinging the stumps laterally out of the way and collecting or piling them in heaps.

AERIAL VESSEL.—C. O. ROWLAND, Chicago, Ill. This improvement relates to aerial vessels, more particularly to that type known as "heavier-than-air" machines, and provides a vessel adapted to navigate in the air, and sets air currents in the atmosphere being employed to control and propel the vessel in addition to driving means provided on the vessel to more easily direct the same.

ADJUSTABLE SHOCK ABSORBING FOOT.—W. MEYEROTT, Middletown, Ohio. This shock-absorbing foot is for use on typewriters, cash registers, or articles of furniture where it is desired to prevent the surface on which the articles rests from being marred, and where it is further desired to deaden the shock incident to the operating or moving of the article and deaden the sound thereon.

AERIAL NAVIGATION.—M. B. SELLERS, Baltimore, Md. The apparatus in this invention has four aeroplanes arranged in stepped form with the highest in front and each of the aeroplanes comprising two so-called wings alongside of each other with the wings of each aeroplane joined together by couplings at their meeting edges. The wings are supported and braced by struts; the frame is supported from the chassis, the latter comprising a combination of sled and wheels so arranged that when the aeroplane is acquiring initial velocity it will run on the wheels and in alighting the wheels rise out of the way, allowing the machine to come to rest on the runners.

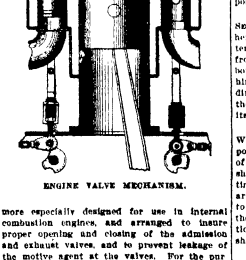
WASHER FOR PEBBLE PHOSPHATE AND THE LIKE.—THOMAS ROBERTS, Charlotte Harbor, Fla. This washer separates pebble phosphate from sand, rocks, etc., with which it is mixed, as generally obtained from the deposit at the bottom of water. It automatically removes and discharges roots and rids pebbles of sand, which it does by first cutting up the roots in order to facilitate their

WASHER FOR PEBBLE PHOSPHATE.

expulsion over a grating. This grating admits of the passage of sand and pebbles through it to conveyers operating in a screened pocket adjacent to the screen on which they discharge. The screen in turn discharges on a second screen leading to the receiver for the pebbles, which is usually a barge. The washer is designed to be located on the upper deck of a dredge, and is shown herewith in a plan view.

SPINDLE LOCK.—M. OMALIA, Scranton, Pa. The more particular purpose here is to provide a lock for preventing the removal of a spindle, such, for instance, as is commonly employed in factory work, from its mounting, yet allowing the spindle all the freedom of motion which it now has, and also permitting the removal of the spindle when the operator sees proper to release the lock.

SELF BALANCED THREAD BOARD.—CHARLES F. WILLIAMS, Greenville, R. I. The accompanying engraving shows a view of self balanced thread boards in position on their rails. The invention relates to ring spinning frames, and the object is to provide a board arranged to permit raising or lowering it conveniently by the doffer taking hold of the



SELF BALANCED THREAD BOARD.

board at any point in the length thereof, and swinging the board up or down, the board in any one of its positions being securely locked in place. For this result, use is made of a counterbalancing lever, a link connecting the lever with the board and a locking device for holding the said lever locked in whatever position it is moved to, on the operator swinging the board into a desired position.

Prime Movers and Their Accessories.

ENGINE VALVE MECHANISM.—OSCAR LAURIN, 4860 Tenth Avenue, Borough of Manhattan, New York, N. Y. The object of this invention is to provide a valve mechanism

ENGINE VALVE MECHANISM.

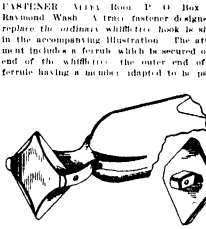
more especially designed for use in internal combustion engines, and arranged to insure proper opening and closing of the admission and exhaust valves, and to prevent leakage of the motive agent at the valves. For the purpose mentioned use is made of a hollow valve for the passage of the motive agent (either live or exhaust), and the valve is adapted to engage a yieldingly mounted cap for closing or opening the hollow valve. In the accompanying engraving a clear presentation is given of the invention in a sectional side elevation of the valve mechanism as applied to internal combustion engines.

RADIATOR CAP.—C. P. ANS, Hoboken, N. J. This invention pertains to radiators, for cooling internal combustion engines. An object is to provide a cap which will condense and return to the radiator any water which may be vaporized by the heat in the radiator, and one which will return to the radiator any water which may be thrown through the vent into the cap.

POWER DEVICE.—T. A. MACDONALD, Clifton, N. J. An object of this invention is to provide a device in which a maximum power is generated from a minimum expenditure of energy. A further object is to provide a wheel or a plurality of wheels, each consisting of a number of blades of particular shape, whereby the motive fluid which is designed to drive the blades is utilized to the fullest extent.

Railways and Their Accessories.

GUIDE BRACKET OR RAIL FOR EDGE WIRE MOVABLE DOORS.—J. M. GRAY, Atlanta, Ga. It is sought in this invention to provide a construction whereby in case the door should become bound in position by the load within the freight car, or otherwise, it can be readily freed and opened, and to provide a construction which will be operative no matter in what position the car may be placed in a wreck or otherwise as it will operate with the car upside down.



Pertaining to Recreation.

MECHANICAL TOBOGGAN SLIDE.—W. F. MANGELS, New York, N. Y. This invention refers to amusement apparatus, such as are used in pleasure resorts, parks, exhibition grounds, and other places, and its object is to provide a new and improved mechanical toboggan slide arranged to afford an exhilarating ride, and to provide means for racing a number of toboggans or sleds starting simultaneously.

FOY.—C. G. PUCKETT, North Bradick, Maine. This invention relates to toys, and more particularly to a toy consisting of a rotary member and a receiver located over it the receiver being adapted to receive sand or other granular substance which upon being released, operate the rotating member for the amusement of children.

Pertaining to Vehicles.

WHIFFLETREE HOOK AND TRACE FASTENER.—ALEX ROSS, P. O. Box 601, Raymond, Wash. A trace fastener designed to replace the ordinary whiffletree hook is shown in the accompanying illustration. The attachment includes a ferrule which is secured on an end of the whiffletree, the outer end of the ferrule having a member adapted to be passed

WHIFFLETREE HOOK AND TRACE FASTENER.

through the eye of the trace, the base of the member being narrow and its outer end widened, the widened end carrying hook projecting side members that receive between them a detachable button and between the side arms of the ferrule member there is formed also a recess which receives a stud on the inner side of the button. A removable fastening pin is passed through the stud of the button and the ferrule attachment to hold the trace in position.

BOTTOM DUMPING WAGON.—M. L. SENDERLING, Jersey City, N. J. A purpose here is to provide a vehicle for carrying materials in bulk, and which is adapted to dump from beneath and to provide a dumping scow bottom, since the bottom, which is in two hinged sections opening sidewise in opposite directions, not only constitutes a bottom for the body, but also has a carrying capacity of its own.

TIRE CONSTRUCTION.—C. N. HARRISON, Westfield, N. J. The more particular purpose of the inventor is to increase the life of the tire by giving the tire tread a desirable shape for the purpose of lessening the continual bending which the tread must ordinarily undergo. The invention further relates to clamping mechanism for holding edges of the tire far apart to give the intervening portion of the tire tread a substantially bow-shaped section.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

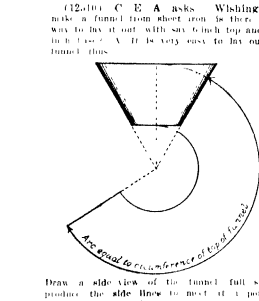
Notes and Queries.

Kindly refer your queries on separate sheets of paper when corresponding about such matters, and write subscriptions books, etc. This will greatly facilitate answering your questions. In many cases they have to be referred to correspondents and the full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full lists of correspondents are printed from time to time and will be mailed on request.

(12,909) I. L. B. writes: You seem to have an idea of heat waves which is not the one accepted by physicists. See Maxwell's theory of Heat. (Longmans, Green & Co., 1902), the lower half of page 10 he defines three modes of heat transference. Then continuing one of these modes on top page 247 he says: Hence all that we have said about the waves of light is applicable to heat radiation which is therefore a series of waves." Rearranging the sentence, we get that a series of heat waves is therefore heat radiation. Then see Preston, Theory of Heat (1904), page 56, top paragraph where he states that all matter at any temperature gives waves of heat. Follow this with page 539 at bottom. We should confine our attention to the process of radiation, which does not appear to depend in any way on the presence of matter, but which takes place through the best vacua, and through interstellar spaces." This sole statement is no original statement that a vacuum is no insulator for heat waves (i. e., radiation. Conduction and convection are eliminated as modes of heat transference as surrounding a body with a vacuum, and the radiation is made as small as possible by using a polished surface. See Preston page 526 article 259, on the radiation of polished surfaces. In regard to the second part of my criticism let me cite "Modern Electrical Theory," Campbell (Cambridge Series 1905) page 106: "And the mean kinetic energy of the molecules in virtue of their speed of agitation is proportional to the temperature of the gas on the absolute scale." Also Schuster, "Theory" by Boynton (Macmillan Company, 1904) page 42: "Two gases are at the same temperature when their molecules have the same mean kinetic energy." In neither case is any reference made to the number of collisions as having any necessary connection with the temperature. In Maxwell's Theory of Heat page 82 we find the equation

$$p = \frac{1}{3}\rho\bar{v}^2$$

v = velocity
σ = volume
p = pressure



And also the statement that $p\sigma$ and $\frac{1}{3}\rho\bar{v}^2$ are proportional to absolute temperature. No term showing number of collisions of molecules is given. The number of collisions per second is given by an equation in Boynton page 50:

$$\frac{I}{T} = \frac{\sqrt{2}\,\pi\,n\,s^2\,\bar{v}}{4}$$

n = number of molecules per $c.c.$
s = one inch cross section of molecule
$\bar{v}$ = velocity of molecule
I = total volume considered
T = time between collisions
$\frac{I}{T}$ = number of collisions per second

Notice that the velocity is only one of four factors that determine the number of collisions per second so that the temperature of a gas and velocity of its molecules must be increased without increasing the number of collisions provided the other factors (for example 24) be changed in the proper ratio. The concentrates on my original statement that the number of collisions is not a necessary cause or result of a rise in temperature of a gas.

(12,910) C. E. A. asks: Wishing to make a funnel from sheet iron is there any way to find it out with say 6 inch top and 2 inch base? A. It is very easy to lay out a funnel thus

Draw a side view of the funnel full size producing the side lines to meet at a point; draw two circles from this point as a center and step off on either of the circles with a pair of dividers set to a small space a distance equal to the circumference of the funnel; then cut out the pattern.

NEW BOOKS, ETC.

THE ENGINEERING INDEX ANNUAL FOR 1910. New York: The Engineering Magazine, 1911. 8vo, 496 pp. Price, $2.

The headings under which this admirable index is based comprise civil engineering, electrical engineering, industrial economy, marine and naval engineering, mechanical engineering, mining and metallurgy, railway engineering, and street and electric railways. A specialist in any one of these branches will find a collation of references to the current literature of his subject. Two hundred and fifty publications are included, representing seventeen peoples and six languages. Every entry is accompanied by a short note defining the scope and purport of the article. This, the ninth volume, completes an index of engineering and technical literature covering twenty-six years, although the first two volumes, 1884 to 1895, are now out of print.

STORAGE BATTERIES: Their Theory, Construction, and Use. By A. E. Watson, E.E., Ph.D. Lynn, Mass.: Bubier Publishing Company, 1911. 16mo, 166 pp., illustrated. Price, $1.50.

In offering a second edition of "Storage batteries" the author endeavors to give within limited space all the essential features and advantages of the modern forms of cells. He sets forth in simple language the theory of the chemical actions involved, gives his own method of making plates tells how to set up and care for batteries, and instructs the reader as to switchboard arrangements. The lead type of cell is dealt with almost exclusively, as being the only really efficient cell on the market. The descriptions of cells have been approved by their manufacturers, so that the accuracy of each description is assured.

TO MARS AND THE MOON. By Mark Wicks. Philadelphia: J. B. Lippincott Company, 1911. 8vo, 328 pp., illustrated. Price $1.50.

The world is beginning to see that there is more romance in science and more science in romance than it has heretofore been willing to admit. Perhaps this fact is sufficient excuse for Mr. Wicks's attempt to take us to Mars in a flying machine. At any rate his pleasing narrative is a medium for the conveyance of the latest discoveries and speculations concerning Mars and its inventions, and he is to be commended for the care with which he has drawn the line between fact and fiction while sustaining at the same time the interest of both. Mr. Wicks has put himself to the trouble of constructing a number of globes reproducing the appearances of Mars at different seasons, and the flying pictures, the plates showing those globes make it easy to follow his description, theories, and arguments. Most people have extremely hazy ideas regarding the relative motions of the earth and the planets, the probable appearance of interstellar space, and the possibility of the existence of life on other worlds than our own. For this majority sugar-coated science is not without value, and the book, put in such a narrative as "To Mars on the Moon," will help them to a better understanding of our solar system and its marvelous machinery.

BEN STONE AT OAKDALE. By Morgan Scott. New York: Hurst & Co., 1911. 8vo, 316 pp., illustrated. Price, 60 cents.

Boys demand incident and action in their fiction. If the story gladdens soon boy being, so much the better. There is plenty of fun and plenty of action in Ben Stone at Oakdale. Ben the hero, is the proverbial boy with a bad name. His plucky stand against adverse circumstances and persecution forms the substance of the narrative. While adventures are encountered and prodigies performed, the probabilities have not been strained to the vanishing point the characterization is kept within the bounds of reason, and inspiration toward fair play and manliness breathes from every page.

THE EXPERT SIGN PAINTER. By A. Ashmun Kelly, Malvern, Pa. A. Ashmun Kelly, 1910. 8vo, 302 pp.

As its title implies, this is a book of reference for practical sign painters and letterers. It is not a collection of fonts and alphabets, but places before the expert workman the varying methods of other expert workmen compiled not alone from the writer's own experience, but from all the published works and current literature on the subject with which he has been able to get in touch. In the historical sketch which introduces the subject the writer makes mention of such well-known men as Benedict Arnold and James Whitcomb Riley. Arnold wielded the brush and pencil on sign-work while living in New Haven and Riley began life as a sign painter. From a general consideration of letters and lettering we pass to the tools of the trade, the pigments, and the construction of the sign board. Special requirements are treated in separate chapters, as the things necessary to be observed in church lettering, in wall signs, in lettering on oil cloth and canvas in silk and satin banner painting, and in smalts and smalting. Work on glass—gilding, pearl leaf enrichment, embossing, and imitation frosting—is given several chapters. Even the prices charged for various kinds of work are given, the office equipment and stationery are taken under advisement, and side-occupations such as glass-drilling, the manufacture of bronze powder and tinfoil, and the silvering of mirrors are dealt with in the concluding chapters of the work.

SOME SMALL HOUSES. By Walter Gray Ross. New York: Frederick Warne & Co. 8vo, 94 pp. Price, $1 net.

"Some Small Houses" was first issued in 1908. That edition having been exhausted, the opportunity has been taken to enlarge the work. There are ninety reproductions of photographs and black-and-white drawings, besides a frontispiece in color, and many of these cannot fail to interest that great proportion of educated people who, as the author truly says, have to make their homes in small houses. It is an English publication, hence the cost estimates given will not apply to this country. Aside from this drawback, however, there is no reason why the designs should not be at least helpfully suggestive to American home-builders, if not to be adopted in their entirety.

COMMERCIAL GEOGRAPHY. By Edward Van Dyke Robinson. Chicago: Rand, McNally & Co. 12mo.; 455 + 48 pp. Price, $1.25 net.

The last decade has seen the publication of a number of commercial geographies which all have more or less merit. The present volume, however, departs rather radically from its predecessors, and being published by a large map and atlas firm, the maps themselves are of the highest order. It is impossible to see how a more complete and useful book on this subject could possibly be written. The beautifully colored maps are not placed at the end of the volume or scattered through the book as inserts, but are actually printed where they belong with the text. The illustrations are numerous and are in the main well executed. The author has performed his task in a thoroughly workmanlike manner, and has produced a book which should be in the library of all persons who are interested in progress, whether they care for a commercial geography or not. The possession of this book will widen the mind of any one. Few people, for instance could tell you much about the Canal Zone. Here we find a map showing the boundary lines, the position of the great datum locks, Panama, Panama Railroad, the Culebra Cut, etc. The treatment is of course regionary. We can recommend this book as being a valuable addition to the library.

THE NEW DICTIONARY OF STATISTICS. A Complement of the Fourth Edition of Mulhall's "Dictionary of Statistics," by Augustus D. Webb, B.S.C., F.F.S. London: George Routledge & Sons, Ltd. New York: E. P. Dutton & Co. Quarto, 682 pp. Price, $7.

"Mulhall" is the great authority which is constantly cited by all statisticians. Unfortunately, however, it is out of date, so that the present volume will be warmly welcomed as a complementary volume. In our own experience we have found that the book on statistics is out of date in certain particulars before the first copy leaves the bindery. "Figures," according to the oft quoted dictum "can prove anything." As a matter of fact, they prove nothing at all. They simply record the success (or attempts to prove) things, and things are but evidences to be examined, weighed, and judged as any other kind of evidence. To this end no explanatory matter, either in the form of footnotes or in the text that may accompany the figures, should be left unread or ignored. This advice from the preface is specially good advice. The author wisely notes that the comparison of international statistics is peculiarly difficult. The expense of producing a book of this kind is so great that it is to be hoped that it will have a considerable sale. The book is very well made.

MODERN METHODS OF WATER PURIFICATION. By John Don, F.I.C., A.M.I., and John Chisholm, A.M.I. New York: Longmans, Green & Co. 1911. 8vo; 368 pp., 96 illustrations. Price, $4.20 net.

This is a review of the different processes of water purification, with a consideration of the extent to which they are justified by results. Much of the existing literature of this subject is in periodical form and in scattered Health Board reports. "Modern Methods of Water Purification" brings together the gist of these scattered papers and presents it in a readily accessible and permanent form. The sources of supply are considered in connection with the means used for the detection of pollution. Storage and the chemical changes it effects are dealt with in a succeeding chapter and the copper sulphate treatment of plant growths is explained. The chapter on the construction of reservoirs is illustrated by diagrams showing basins in this country and in England. Sand filtration and the management of sand filters is given space equal to almost a fourth of the entire volume. Mechanical filters the ozone process, water-softening and household appliances, the testing of water, and the problems of distribution are treated in the latter part of the work, which concludes with filtration constants and data, tables, and a short bibliography. Water purification is a subject of growing interest and great importance. The work in hand is timely and comprehensive.

LEGAL NOTICES

PATENTS

INVENTORS are invited to communicate with Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D. C., in regard to securing valid patent protection for their inventions. Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured.

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our Hand-Book on Patents will be sent free on request.

Ours is the Oldest agency for securing patents: it was established over sixty-five years ago.

MUNN & CO., 361 Broadway, New York
Branch Office, 625 F St., Washington, D. C.

PATENTS SECURED OR FEE RETURNED
Free report as to Patentability. Illustrated Guide Book, and What Inventors Want, List of Inventions Wanted and Prizes offered for inventions sent free. VICTOR J. EVANS & CO., Washington, D.C.

Classified Advertisements

Advertising in this column is 15 cents a line. No less than four nor more than 15 lines accepted. Count seven words to a line. Cash with order must be accompanied by a remittance. Further information sent on request.

HELP WANTED.

SUPERINTENDENT.—Metal Department of a large manufacturing concern. One who thoroughly understands the making and finishing of Aluminum sheet metals. No one who is not thoroughly experienced need apply. Permanent position to right party. Address Metal Expert, Box 773, N. Y.

WANTED.—A first-class American automobile mechanic to take charge of a garage. Must be an up-to-date Garage Foreman state experience. Address Thomas & Co., Newburg, N. Y.

PATENTS FOR SALE.

FOR SALE, U. S. Patent, No. 957,261, Automobiles (tool Consists of lifting jack, pin, shovel, box and boom bar. Nothing like it on the market. Address J. A. Baird and William Patent, Jackson, Ga.

SUCCESSFUL TRIPLEX STRETCHER.—U. S. patent. Easy to make. Sells to every man. For further particulars address, S. Bantlow, 401-403 Masely Tushner Building, Portland, Oregon.

WANTED.

LOCAL REPRESENTATIVE WANTED. Splendid income assured right man to act as our representative after learning our business thoroughly by mail. Former experience unnecessary. All we require is honesty, ability, ambition and willingness to learn a lucrative business. No soliciting or traveling. This is an exceptional opportunity for a man in your section to get into a big paying business. Write, stating age and present independent for life. Write at once for full particulars. Address, E. R. Marden, Pres. The Marden Co-Operative Real Estate Company, L 276, Marden Building, Washington, D. C.

WANTED, ADDRESSES OF USERS OF GRAPHITE in Slate, Soapstone, Hydraulics and Putter's Earth in both crude and manufactured state. For particulars, address Howard and Company, Savannah, Ga.

MISCELLANEOUS.

FREE—"INVESTING FOR PROFIT" Magazine. Send me your name and I will mail you this massive absolutely free. Regular price one dollar everywhere—get this meantime. It is worth $5 a copy to any man who cares to invest a few dollars wisely. Tells you how $1,000 can grow to $12,000 in three years. Explains the Compound Interest the Real Earning Power of your money. This magazine six months free if you write at once. H. L. Barber Publisher, 426, 28 W. Jackson Blvd., Chicago.

$30 INDEPENDENT—Start. Money Making Mail Order Business at Home. Particulars free. No text that may accompany the figures, should be left unread or ignored. This advice from the preface is specially good advice. The author wisely notes that the comparison of international statistics is peculiarly difficult. The expense of producing a book of this kind is so great that it is to be hoped that it will have a considerable sale. The book is very well made.

Civil Service Drawing. Engineering, descriptive writing, agricultural, poultry, fruit growing, mechanical drawing, shorthand courses. Manufacturing. Tuition free. Write for booklet. Apply to Carnegie College, Rogers, Ohio.

LISTS OF MANUFACTURERS.

COMPLETE LISTS of manufacturers in all lines supplied on short notice at moderate rates. Small and special lists compiled to order at various prices. Descriptive circulars mailed on request. Address Munn & Co., Inc., 361 Broadway, New York.

INQUIRY COLUMN

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once, and by referring to the name and address of the party desires the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated. MUNN & CO., Inc.

Inquiry No. 9245.—Wanted, addresses of parties having raw materials or materials containing potash in any form.

Inquiry No. 9247.—Wanted, to buy a Paraffine serrated wafer.

Inquiry No. 9254.—Wanted, the name and address of manufacturers of lead pencils and pen holders, such as are used for advertising purposes.

Inquiry No. 9255.—Wanted by a patent solicitor, a ball-bearing axle, which could be purchased on a royalty basis; it must be cheap and fairly proved.

Inquiry No. 9261.—Wanted addresses of parties having Phillipine agencies, or able to ship one.

Inquiry No. 9262.—Wanted addresses of firms selling second-hand paper machines.

Inquiry No. 9263.—Wanted addresses of parties having some association to offer in any part of the world.

Inquiry No. 9264.—Wanted, to buy a sawmill and operating the cutting of a timber.

Inquiry No. 9265.—Wanted addresses of parties able to ship creosote, phenol, lime, cement or any chemical suitable as an extractive.

The New Era of Blood-transfusion

(Continued from page 125)

fastened into that one of the two grooves on the ring which happens to be nearest to the handle (See Crile method.) The artery is then drawn over the vein so its inner surface touches the cuff, and is fastened into the remaining groove. This lining of the two blood-vessels thus meet as in the Carrel suture.

Crile experimented upon hundreds of dogs before operating upon a single human being, and has been roundly abused for his pains by the anti-vivisectionists. There being obvious danger to the giver from anæmia, and danger also that the heart of the patient might be filled so full that it could no longer pump, Crile wanted to know just how much blood might be lost and received.

The heart requires a certain volume of fluid (blood) in the vessels in order to have enough to pump on. In severe hemorrhage, temporary relief is given by filling up the vessels with salt water (saline-solution, infusion, as it is called). The salt water cannot replace the blood, but it gives the heart something with which to pump, and so tides the body over the emergency. After a time, the salt-water leaves the body through the kidneys, and the patient is as badly off as before. This is not the case with transfused blood, that stays in the vessels.

There is another condition known as "shock," in which although the blood stays in the vessels, the heart has just as much difficulty to pump as though there had been a bad hemorrhage. The reason is because the shock, the injury to the nervous system causes a paralysis of the nerves known as vasomotor. The result of this paralysis is that the blood-pressure disappears just as though a severe hemorrhage had removed the blood, and Crile has shown that, also for this condition, transfusion is the best remedy we have.

A man may be so injured by machinery as to require an immediate operation, but he has lost so much blood that his remaining strength may give way; transfusion rectifies the condition by supplying a sufficient quantity of red blood-cells to combine with the oxygen of the air and give back the oxygen to the tissues. Crile says that recovery from hemorrhage is largely a problem in mechanics, as andrenalin has been added to the circulation even after death, and the heart action substituted by manual pressure—and blood-pressure thus made to rise. We all know when a man is poisoned by gas that the red coloring matter (three hundred times as greedy of carbon-monoxide as of oxygen) has been displaced. Thus the blood is destroyed, and new blood, through transfusion, furnishes a certain corrective, if not delayed too long.

Research on the Blood.

Denys in the 17th century advocated the use of animal blood in transfusion, maintaining that as the animal lives more closely to a state or nature, his blood must be purer than man's, and answered arguments against it by inquiring why the meat we eat and the milk we drink does not act deleteriously. In view of modern blood-tests, his attitude is instructive as showing what plausible fallacies may be advanced if reasoning, as such, be not corrected by experience.

In 1821, Dumas and Provost gave out the results of their studies on the chemical properties of the blood, showing that when the bloods of different species were mixed, even though the globules were of the same size but of different dimensions, animals rarely lived longer than six days. The blood of an animal with circular corpuscles injected into a bird caused the death of the bird with symptoms of violent poisoning.

In 1875, Landois showed precisely what takes place when the blood is thus mixed. The red corpuscles are dissolved by the poisoning of the protoplasm, and the hemoglobin (coloring matter) exuded from the envelope. Under the microscope, the first stage of this condition (hemolysis) shows the corpuscles beginning to swell. The injection of certain chemicals causes the same phenomenon, and hemolysis occurs on artificial heating or freezing of blood. The consequence is the breaking down of the cell-wall. This objective demonstration, as might have been expected, put a stop to the use of animal blood in transfusion.

Modern transfusion shows that while the blood of one healthy person does not poison the blood of another healthy person, the blood may acquire such power through certain diseases, since the disease may act in such manner as to change it. In this case, too, there is a dissolving of the cells by blood which, though apparently normal, in reality is not. If the sick man's blood has this property of dissolving (hemolyzing) the blood-cells of the giver, the new blood will do him no good, as it will be destroyed as rapidly as it is transfused. If by an oversight the blood of the giver has this property, the transfusion will be even more dangerous, as the new blood will destroy that already present in the patient's vessels. By testing the two bloods against each other this danger may be avoided.

Another peculiar property of the blood is what is called agglutination, known only since 1900. When the bloods of two different persons are mixed, they often have the effect of making the blood-cells clump together in tight little masses. Landsteiner showed that all human beings fall into four sharply defined classes in this regard, and that agglutination may be explained by assuming the existence of two agglutinins, of which the second group possesses one, the third group the other, the first group both, and the fourth neither. When the blood of persons belonging to any one class is mixed with the blood of a person belonging to any of the other three classes, agglutination occurs, but this is avoided if the blood test shows that the giver and receiver of the blood belong to the same class. This is a hereditary quality, and an examination of seventy-two families shows that the agglutinins follow Mendel's law.

It is evident that if blood were transfused from a person belonging to one of the classes referred to, into the vessels of a person belonging to any one of the other three classes, the clumps likely to form would cause a stopping up of the blood-vessels and thus serious trouble. Indeed Ottenberg is investigating further the phenomenon of agglutination at Columbia College and Mt. Sinai Hospital at the present time. Medical opinion is that performing the agglutination-test for transfusion may, in many cases, make all the difference between a transfusion that is successful and one that means merely a waste of human blood.

Formerly, the patient often became worse after the operation; indiscriminately taking blood from anyone willing to give it was a contributing cause. Now when members of the family are rejected, for the reasons outlined, advertisements are put in the newspapers; fifteen to twenty respondents, at that, often being rejected as unfit to serve, and the one selected whose blood has the least or no toxic action. The person who gives his blood must be strong enough to lose it and he must have no blood-disease, by which it would appear that even selling one's blood is not by any means as easy as might be supposed.

The Current Supplement

THE mounting and grouping of exhibition specimens as practised at our National Museum of Natural History, has developed into a fine art. A particularly striking group of fossil remains of the great ground-sloth has just been completed, and in the current SUPPLEMENT, No. 1857, Mr. Beasley tells us about these giants of the past, and the good work accomplished in setting up in realistic arrangement these representatives of an age long gone by.—In questions relating to social conditions it is unfortunately very difficult to arrive at thoroughly objective conclusions, independent of subjective bias, and therefore accepted by all who devote serious thought to the subject. An attempt to apply objective methods of scientific experiment to questions of labor and wages is reported on in a very interesting article by D. A. Imbert.—That the time of day varies from place to place on our globe is a fact known to every schoolboy. But with all the details of the circumstances, which determine the "true solar day," probably not very many of us are acquainted. An article contrib-

Judge the Quality of an Automobile by the Speed Indicator It Carries

SINCE we told the public where to look for the outward evidence of inward quality in a car, the Automobile Buying and Using Public has been *Looking for the Speed Indicator.*

Now Note the Result—

They have found (as we said they would) that the car with the Warner on the dash was almost invariably good and reliable. And on the other hand, that the great proportion of the cars they examined which had inferior and unreliable speed indicators on them were acknowledged by those who *know cars*, to be inferior and unreliable automobiles.

The only excuse a manufacturer of a good car can offer for putting on an inferior and unreliable speed indicator as equipment is *price*.

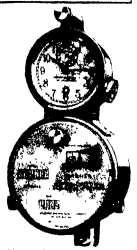
Buyers reason that if such a manufacturer is willing to save money so glaringly in one place that there is room for reasonable doubt as to the quality of the car in other respects.

To get a line on the real quality of an automobile, *look for the speed indicator.*

The Warner Auto-Meter is the highest priced speed indicating instrument made. It is a true instrument in every sense. It is known to be sensitive, accurate and reliable. Hundreds of users have transferred them Warner to the sixth and seventh car. These Warners have indicated a mileage up to 90,000 and 100,000 miles—yet are as reliable as when new.

The Warner on the dash indicates the intention of the manufacturer or owner to value quality above price—to give or have *the best.*

Reliable manufacturers are consequently equipping or recommending the Warner Auto-Meter with their cars. Other manufacturers and their agents and dealers are figuring how to give a convincing answer to the buyer who asks this question.



"How can any car manufacturer claim that he uses the choicest and best of everything throughout his car when the speed indicator—the most-looked-at thing on the car—is known to be cheap, unreliable and inferior in every way?"

Motorists are becoming more and more persistent in asking this question and patiently waiting for an answer. Such have little difficulty in getting with their cars an accurate, reliable and wondrously durable

WARNER AUTO-METER

"The Aristocrat of Speed Indicators"

THE Warner can be secured through reputable Automobile dealers in any city or town in the United States. Warner branches are maintained in all the principal cities for the convenience of these dealers and their customers. Inquiry to Beloit or at our branches is invited for Warner literature.

Model M2, Price $125
Other Models from $50 to $145

Curtiss Aeroplanes Motor

uted by Professor F. R. Honey, of Trinity College, elucidates these points.—Lieut.-Col Hubner writes on "Combination Projectiles," a field in which recent years have brought developments exceeding some of the earlier expectations.—"There is to-day a growing tendency," says Mr S S Hough in his article on "Photography an Aid to Astronomy," "to replace the human eye at the end of the telescope by the photographic camera" The advantages thus gained, and the historical development of astro-photography are set forth by the author.—A new portable gasoline air-compressor suitable for inflating pneumatic tires is described by Mr. F C Perkins.—In an article originally published in the *Umschau*, Professor Zuntz gives an account of a new respiration calorimeter used at the Agricultural School at Berlin for investigations in the physiology of nutrition and animal work.—There is also an article by J W T Duval on a moisture tester for grain and other substances.—The second and concluding instalment of the paper by W H Dines on "Practical Applications of Meteorology to Aeronautics" appears in this issue, as does also the second instalment of Donald Murray's article on "Printing Telegraphy"

The Split-log Drag in Road-making

THE public roads bureau of the Department of Agriculture has estimated that there are 2,000,000 miles of earth roads in the United States and has suggested an inexpensive way for their improvement The split log drag is its solution of the problem, and from time to time the bureau issues bulletins in forming the farmer how to make it

The main thing needed is a dry red cedar log, although red elm and walnut are useful for the purpose, while box elder, soft maple, or even willow may be employed Oak, hickory and ash are not recommended

The log, seven to ten feet long and ten to twelve inches in diameter at the butt, is split as near the center as possible, the larger piece being used as the front of the drag and sometimes being shod with iron along the lower or cutting edge

The two slabs on edge and thirty inches apart are fastened together by stakes in such a way that when the drag is in use on one side of a road, the end of the back slab is about sixteen inches nearer the center of the drive-way than the end of the front slab This gives what is called the setback Between the heavy slabs and resting on the connecting stakes is a board on which the driver stands

A team of horses is hitched to this completed drag in such a way that the drag unloaded will follow at an angle of about forty-five degrees The teams should be driven with one horse on either side of the right hand wheel track or rut the full length of the part to be dragged, and made to return in the same manner over the other half of the roadway Such treatment will move the earth toward the center of the roadway and raise it gradually above the surrounding level

There is recommended the use of the split log drag after heavy rains, when the road should be gone over once each way, but much depends on the quality of the soil, some roads requiring frequent treatment

The method is said to be most economical

A Peculiar Well.—The attention of the Geological Survey having some time ago been called to a peculiar well in Ohio, an investigation thereof was made. The well produces both fresh and salt water through two separate pumps. The explanation proved to be quite simple Two water bearing beds, confined between layers of limestone, occur at this point, one above the water The pipe of the fresh-water pump taps the upper vein at a depth of sixteen feet The pipe of the salt-water pump touches the lower vein at a depth of thirty-five feet; and the brine, being heavier than the fresh water, does not mix with it, but remains at the bottom.

Aeronautics

The European Circuit Race.—The 1,074-mile Paris-London-Paris Circuit race, which started so disastrously, on June 18th, was finally ended on July 7th. Nine aviators out of the 41 who started succeeded in finishing. The race was won by Lieut. Conneau in his Blériot monoplane, his time being 58 hours and 38 minutes. His actual flying time was 24 hours, which corresponds to an average speed of nearly 45 miles an hour. Roland Garros was second in his Blériot monoplane with the time of 62 hours, 17 minutes, 16 2/5 seconds. Vidart, in his Deperdussin monoplane, was third, in 73 hours, 32 minutes, 57 3/5 seconds. Vedrines, in his Morane monoplane, came fourth in 86 hours, 37 minutes, 2 seconds. Gibert, on an R. E P monoplane, finished fifth, and Kimmerling, on a Sommer monoplane, sixth. Their times, respectively, were 89:42.34 3/5 and 93:10: 24 2/5. Maurice Farman biplanes, driven by Renaux and Barra, were seventh and eighth, respectively, their times being 110:14 05 2/5 and 206 21'58. The former aviator was the only one who finished the entire race carrying a passenger Tabuteau, with a Bristol (English) biplane, was the ninth and last to finish. Valentine, an Englishman, flew his Deperdussin monoplane as far as London, but abandoned the race at that point. This race was the greatest test of endurance that has ever been given the modern aeroplane Flights were made in wind, rain, and fog The greatest elimination occurred in the first stage, in which 23 machines dropped out. The second, third fourth, and fifth stages saw the dropping out of one, three, two, and two machines, respectively, while ten completed the seventh stage and arrived at London Some of the stages were flown at a speed of over 60 miles an hour

A Flight Across New York City.—On July 8th, Ladis Lewkowitz, a Russian aviator who had previously made a 6,000-foot altitude flight at Nassau Boulevard Aerodrome with his Blériot monoplane fitted with a 50-horse-power Anzani motor, ascended at that place and flew to New York He came above the East River at the Queensborough Bridge and flew up the River to Harlem at a great height. When crossing over the city at an altitude of between 8,000 and 9,000 feet, his motor stopped and the aviator was obliged to *volplane*. This he did with such good results that he crossed the Hudson River and landed in a marsh back of Leonia, some six miles away from where the motor gave out His flight and that of Atwood are the only two flights which have been made above New York since the Statue of Liberty race last October

A Record American Cross-Country Flight.—A flight somewhat in line with the great long distance races recently held abroad was made the first part of last month by Harry N Atwood, the young Boston aviator After having made numerous cross-country trips in the vicinity of the Hub, Atwood flew with his mechanic from Boston to New London, Conn.—a distance of 110 miles—in 2 hours and 10 minutes on June 30th. The trip was made without a stop and in the afternoon the young aviator took aloft the mayor of New London and flew above the Yale-Harvard Varsity boat race. At 7 o'clock the next morning, he started for New York, which city he reached in about 3¼ hours without a stop *en route*. After alighting and refilling his fuel tank at Astoria, he flew down the East River and across the sky scraper section of Manhattan Island, finally alighting with precision upon Governor's Island. On July 4th he flew the 110 miles to Atlantic City in 5¾ hours, which included several stops for gasoline He was buffeted by extremely strong head winds all the way. His machine fell in the sea and was demolished when he and Charles K. Hamilton were making an exhibition flight together at Atlantic City, but he persuaded Hamilton to lean him the latter's Burgess-Wright biplane for the balance of the flight. Hamilton had his aeroplane towed over the road from Waterbury, Conn., to Atlantic City, which was also completed in about a day, and the next morning he and Atwood resumed their

Used today by Pres. Roosevelt, Admiral Dewey, Rockefellers, Vanderbilts, Gladstone, Pulitzer, Marconi, Astors, Goulds, Edisons, Wanamakers, Burbanks, Depews, Schwabs, Carnegies

journey toward Washington On account of the great humidity they found extreme difficulty in rising more than 150 feet and they were finally obliged to alight near Baltimore because of their inability to clear trees and buildings The following day (July 11th) Atwood and Hamilton covered the 40 miles remaining between Stemmers Run and College Park in the early morning hours without mishap Three days later he finished his 576 mile trip to Washington and alighted on the lawn of the White House, where he was greeted by President Taft In all he took two weeks in which to cover the distance whereas in the recent circuit race in England, twice this distance was covered in but 31½ hours elapsed time by Lieut Conneau in his Blériot monoplane

Science

Cranes and Herons in Surgery.—Many substances have been employed in turn for making sutures in surgery Such substances must possess peculiar properties which are not readily found Of recent years there has been recommended and used a new material of this kind the tendons of the legs of cranes and herons The tests show that these tendons are particularly well suited for surgical use They are said to form excellent ligatures and are readily absorbed after the wound has healed

The Exploration of Dutch Guiana.—The expedition that set out from Paramaribo in July, 1910, to explore the only part of Dutch Guiana not previously known to the civilized world—viz, the upper Corentyn and its tributaries—after suffering the loss of its leader Eilert de Haan, achieved the object of its labors most successfully under Lieut Kayser This expedition was the last of a series that have been working for the past 15 years, under the auspices of the Geographical Society of the Netherlands, in making a complete exploration of the colony

Color Photographs of Atmospheric Phenomena —The improvements and simplifications lately introduced by Messrs Lumière in the process of color photography were the subject of a recent address by M Léon Gimpel before the Astronomical Society of France The method of development has been greatly facilitated by the use of a green light obtained by applying "Virida paper to the lantern, while magnesium light is used in printing and an unlimited number of prints may now be easily produced Instantaneous pictures are readily taken with plates made hypersensitive according to the method of Simmnen and Thovert M Gimpel has applied these various improved methods with great success to the photography of meteorological phenomena — thunderstorms, rainbows fogs, inundations auroras sunsets etc and in the course of his lecture he threw on a screen a number of beautiful pictures of this character

Aerological Observations in Java.—Dr W van Bemmelen has published in the *Meteorologische Zeitschrift* a report on the *ballon-sonde* observations made near Batavia during the year 1910 They are the most extensive series of such observations heretofore made within the tropics, and the results are in satisfactory agreement with those obtained by Berson, in German East Africa in 1908 The stratosphere was reached several times at altitudes ranging from 15 to 18 kilometers and with temperatures ranging from —67 deg C to —83 5 deg C the latter being the lowest temperature recorded, and with the exception of Berson's reading of —83 9 deg C, the lowest ever observed in the atmosphere Such readings are however, uncertain to the extent of some degrees at the great altitudes in question. The average thickness of the westerly monsoon wind was found to be 5 5 kilometers Many difficulties in the technique of the observations were only partially overcome, but there is every reason to hope that the excellent work in aerology now being carried on by the Dutch observers in Java will in a few years fill the serious gap that has heretofore existed in our knowledge of the upper air, due to the neglect of this class of investigations within the tropics.

Valuable Books

The Scientific American Cyclopedia of Formulas

Edited by ALBERT A. HOPKINS Octavo, 1077 pages 15,000 Receipts. Cloth, $5.00; half morocco, $6 50

¶ This valuable work is a careful compilation of about 15 000 selected formulas, covering nearly every branch of the useful arts and industries Never before has such a large collection of valuable formulas useful to everyone, been offered to the public Those engaged in any branch of industry will probably find in the volume much that is of especial use in their respective callings Those in search of salable articles which are in demand, factured on a small scale, will find hundreds at least excellent suggestions. It should have a place in every laboratory, factory and home

Concrete Pottery and Garden Furniture

By RALPH C. DAVISON. 16mo , 196 pages, 140 illustrations. Price, $1 50

¶ The book describes in detail in a most practical manner the various methods of casting concrete for ornamental and useful purposes. It tells how to make all kinds of concrete vases ornamental flower pots, concrete garden seats, concrete benches, concrete fences, etc. Full practical instructions are given for constructing and finishing the different kinds of molds, making the wire forms or frames selecting and mixing the ingredients, covering the wire frames, modeling the cement figure into form, and casting and finishing the various objects. With the information given in this book, any handy man or woman can make many useful and ornamental objects in cement for the adornment of the home or garden The information on color work alone is worth many times the cost of the book.

Handy Man's Workshop and Laboratory

Compiled and edited by A. RUSSELL BOND. 12mo., 467 pages, 370 illustrations. Price, $2 00.

¶ This is a compilation of hundreds of valuable suggestions and receipts, ideas by a practical man of those mechanically inclined, and tells how all kinds of jobs can be done in the handiest possible and most economical ways The methods are practical, and the solutions to which they relate are of frequent occurrence. It may be reported as the best collection of this kind of information published, and appeals to all those who find use for such either in the home or workshop. The book is fully illustrated, in many cases with working drawings, which show clearly how the work is done.

Any of these books will be sent, postpaid, on receipt of advertised price

To Motorists who are about to renew their tire equipment

There is no reason why you should spend more money for tires than do the thousands of motorists who use UNITED STATES TIRES

You are in a position now to *choose* tires, not merely *buy* them

When you purchased your new car, you naturally took the tires that came with the car But now you can judge tires for yourself You know the sort of tire service tires ought to give and you know whether or not the tires you have been using have sufficient strength to *measure up* to that standard

Probably the best reason why thousands of motorists are today forsaking other brands and turning to

United States Tires

Continental G & J Hartford Morgan & Wright

is because they are coming to realize that by combining *in each tire* the strongest points of *four famous makes*, United States Tires are unquestionably

The Strongest Tires in the World

and that this *extra strength* means far more tire mileage with far less tire trouble than they have been accustomed to in the use of other brands

The oft quoted statements, "Have always used them," and "Were on my car when I bought it" are mighty poor reasons (if they are the *only* reasons) for continuing with *any* brand of tires

If tire *expense* means anything to you, disregard all other reasons and demand the tires that are *actually giving* users of United States Tires the kind of service that *every motorist wants*

It is this extra service, *without extra cost* that has made United States Tires

America's PREDOMINANT Tires

You can buy them anywhere—four fifths of all the best dealers handle them Made in every style and size —American and Millimeter

The reason why—

the Scientific American holds its old readers and is gaining in circulation so rapidly is that it is *interesting* We recently asked our subscribers to send us the names of people whom *they* believed the Scientific American would interest and the "interestingness" of the magazine is demonstrated by the large number of the names so received which have been added to our regular subscription list Have you sent us a list? If not

Here is the way:

Simply send us the names and addresses of the people whom you think will be interested and we will do the rest An accurate record of all names received in this manner is kept and for each new subscription got from any list we extend the subscription of the person who sent us the list for four months Thus if we receive three new subscriptions from any one list the subscription of the person who sent us the list will be extended for a full year

Of course you may send as many names as you wish, the greater the number of names you send the larger the number of subscriptions we will probably receive and the longer the period for which your own subscription will be renewed

Be careful to write the names and addresses plainly and don t fail to put your own name and the address at which you are receiving the Scientific American on each list you send

Address all lists to the Circulation Department, Scientific American 361 Broadway, New York.

AN IDEAL MAGAZINE FOR THE IDEAL HOME

American Homes and Gardens

gives its readers the experience of experts in solving the most difficult home problems. It is a thoroughly practical magazine, having the word *home* for its keynote

How to Build the Home

Floor plans and details of construction of houses of moderate cost as well as more pretentious mansions are a feature of each issue.

How to Decorate the Home

The most experienced decorators in the country describe how the best and most artistic results are attained from the point of expenditure and the more important one of satisfaction

How to Plan and Lay Out the Garden

The frame of the house-picture is the garden and success in its treatment means that each tree and shrub is correctly placed as well as properly grown hence this department will be found most helpful

Outdoor Life and Amusements, Articles on House Industries

Every phase of country life is authoritatively discussed from month to month in its pages. American Homes and Gardens is conceded to be the handsomest magazine published in America. Its beautiful cover printed in colors changes each month, and is always a work of art. Subscription price, $3 00 per year

CONSERVATION

The AUGUST Magazine Number of the SCIENTIFIC AMERICAN issue of AUGUST 12th, 1911

The next magazine number of the Scientific American, August 12th, 1911, will contain a series of articles by leading authorities, which will deal with this vital subject of the conservation of our natural resources

Ex Chief Forester the Hon Gifford Pinchot, whose earnest fight for the preservation of the coal lands of Alaska has led to a favorable decision of the Land Office, which greatly strengthened the cause of conservation, will open the number with an article on the Conservation of our Forests

The Director and Chief Engineer of the Reclamation Service, F H Newell, will write a general article on the past work and future plans of the Reclamation Service

The Director of the Bureau of Mines, Dr Joseph A Holmes, will show that the waste of our supplies of coal is due not merely to careless and extravagant management in the mining of the coal, but also and very largely to methods in burning the fuel.

Dr David T Day, of the United States Geological Survey, will prove, in an article on the conservation of oil and gas, that, as with coal, so with oil and gas, it is possible to effect large economies by judicious management in the oil and natural gas fields and by the use of improved appliances in burning these fuels either for light or power purposes

Dr Hugh M Smith, Deputy Commissioner of Fisheries, will contribute an article on the Conservation of Fish, Oysters, etc., and Seals Conservation is a word to which we are liable to give too restricted an application.

In addition to the above articles, the August 12th number will contain the usual Editorial, Aviation, and other departments.

Important—

When sending us lists of names

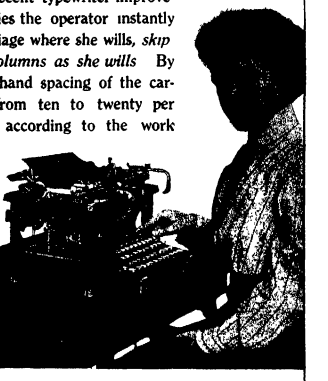
In order to receive credit on your own subscription our friends are reminded that the name of the person sending the list should be distinctly stated on each sheet.

Of course you may send as many names as you wish, the greater the number of names you send the larger the number of subscriptions we will probably receive and the longer the period for which your own subscription will be renewed

It has given us much pleasure to extend the subscriptions of many of our subscribers who in response to our suggestion sent us lists of the people whom they thought the Scientific American would interest. This is gratifying to us not only because the co-operation of our subscribers is of the greatest assistance to us in increasing the circulation of the Scientific American, but also because it assures us that the improvement made in the magazine is meeting with the approval of our readers Have you sent us a list? If not,

Here is the way:

Simply send us the names and addresses of the people whom you think will be interested and we will do the rest. An accurate record of all names received in this manner will be kept, and for each new subscription we get from any list we will extend the subscription of the person who sent us the list for four months Thus if we receive three new subscriptions from any one list the subscription of the person who sent us the list will be extended for a full year.



Be careful to write the names and addresses plainly and don't fail to put your own name and the address at which you are receiving the Scientific American on each list you send

Address all lists to the Circulation Department, Scientific American, 361 Broadway, New York.

Why inch along like an old inchworm with that antiquated hand spacing of the typewriter carriage when you can go right to the spot with a single touch on a Column Selector key of the model 10

Remington

The Remington Column Selector is the greatest of all recent typewriter improvements It enables the operator instantly to place the carriage where she wills, *skipping as many columns as she wills* By eliminating the hand spacing of the carriage it saves from ten to twenty per cent. of labor according to the work to be done

And this is only one of a score of notable improvements on the model 10

Quit paying garage rent or storage bills. Have your auto handy and safe in a fireproof garage of your own.

Here is a garage, as strong, durable and handsome as masonry and even greater in its protection—but *costs only one third to one half as much*

THE PRUDEN GARAGE is the *only* portable garage that is *absolutely proof* against fire—also against damp, lightning storm or vandalism It is no flimsy wooden frame affair covered with sheet iron or canvas *Not a piece of wood in it*—but entirely made of heavy galvanized steel Won't rust or corrode As substantial as granite Lasts a life time yet can be set up or taken down at your will You can put up the Pruden Garage yourself in a few hours, without previous experience. The

PRUDEN SYSTEM OF PORTABLE FIRE Proof CONSTRUCTION

Makes this easy The units are machine fashioned and fit together closely and accurately Our plans and instructions make erection simple

Between Pruden and other portable garages, there is no comparison—if you care for real protection If your car is worth protecting at all it is worth Pruden protection. Almost every day the papers report the burning of garages and the loss of autos. A gentleman in Winnipeg recently lost his Winton while a Pruden Garage was on its way to him. Don't take any chances of loss The money you put into rent, and garage bills, will in a year or two pay the cost of a Pruden Fireproof Garage and absolute safety

Mail Coupon for Catalog Today—

Be sure to give name and model number of your car We can then write you fully as to the size and style of Pruden Garage we recommend for your use. All Pruden Garages are rigidly guaranteed. Mail the Coupon today

SAVE

Make Electricity your servant

TRUE conservation consists not in a closely limited disposition of our natural resources, but in a liberal use of nature's gifts, *intelligently*.

Electricity, one of the most powerful of known forces, has been commercially, economically and intelligently "tamed" to fit the varying needs of our present day living.

In this field the practically unlimited factory, engineering and laboratory equipment of the General Electric Company, has enabled this company to maintain the most conspicuous lead.

Our new Mazda Lamp, with a drawn wire filament —the realization of long and costly experiment— consumes only half the energy required by the old carbon lamp; the saving thus effected is available for other electrical "helps" by which time and labor is conserved.

The Electric Flat Iron, saving many a weary step and much drudgery; the Disk Stove, conserving human energy in addition to its convenience; the Electric Toaster, making crisp, brown toast right on your breakfast table; the Electric Coffee Percolator, making coffee as it should be made; the Domestic Range, the Radiator, etc; —all with a trend toward economy and the saving of energy and labor.

And in the Industrial field,—the Electric Soldering Iron; the Electric Glue Pot; the Electric Oil Tempering Bath, etc.; simplifying and furthering the progress of production.

In the home and in the shop, G. E. Electric Heating Devices mean working under greatly improved conditions—the housewife, the workman accomplishing better results to the greater satisfaction of all concerned—a true conservation of time, money and labor.

Write for a sixty page illustrated price list of domestic and industrial heating devices. **Address Dept. 59-H.**

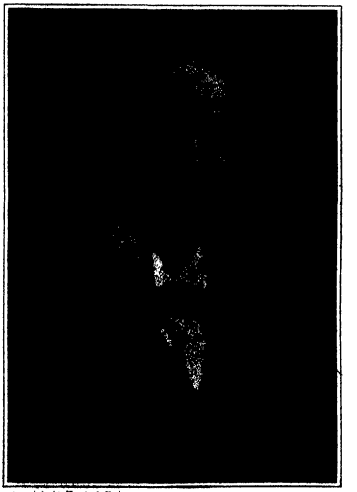
Lookout station for forest fires in a national forest.



The Conservation of the Forests

A National Duty to Protect the 80 Per Cent of Standing Timber Now in Private Hands

By the Hon. Gifford Pinchot, Ex-Chief Forester

FOUR-FIFTHS of the timber in the United States is in private hands. Its preservation depends absolutely upon what the owners choose to do with it. The owner of any part of it may allow his trees to stand uncut or he may cut them under the prevailing method of destructive lumbering so that a new forest will not replace the old or he may consider his timber land as a permanent factory of wood and apply the principles of forestry. This last is what the public welfare requires that he should do but less than two per cent of the privately held timber lands of the United States are now being conservatively handled. With the threat of a timber famine so clearly before us that no man can deny the danger we are treating four-fifths of our timber in the way best calculated to bring on that famine with the least possible delay and in the most aggravated form.

It is by no means wholly the fault of private timber land owners that they do not practise forestry. To practice forestry is to engage in a manufacturing business, the product of which is wood. Now no manufacturing business can succeed unless the products of the factory will bring more in the market than they cost to produce. This is not generally true to-day of the product of the forests. The enormous accumulation of raw material (standing timber) which cost us of this generation nothing to grow in the first place, is the chief reason why the finished product (lumber, etc.) sells to-day in the United States for less than it would cost to grow, harvest, and manufacture it. This is not true in France, Germany or other countries where forestry is practised. Under the laws and economic conditions which there obtain, a timber land owner who grows wood for the market makes a reasonable interest on his money.

Copyright by Harris & Ewing

Hon. Gifford Pinchot, ex-chief forester

Forestry like any other industry must become financially attractive before business men will take it up and several basic conditions must be supplied before it can become so. For example there must be a reasonable security against forest fires. As long as there is excessive danger that the investment may go up in smoke the attractiveness of a long time investment in growing wood must be very seriously reduced. There must be reasonable taxation under which there will be a fair chance to make the business pay. The land upon which the trees grow should be taxed annually but the growing forest crop itself should be taxed only when it is ripe for cutting. Other crops like corn pay but one tax before harvest. Under present methods of taxation the timber crop may pay fifty or one hundred.

There must be fairly uniform conditions imposed upon all competitors in the same market. While the difference in cost between conservative lumbering and ordinary destructive lumbering is but small it is often sufficient to give one of two competitors control over a market to which both are seeking. Thus if a State should require its lumbermen to burn their slashings protect young growth and generally to keep their forests in productive condition while the State which imposed such conditions would be at a great permanent advantage the lumbermen who were obliged to practise them would be at a slight and temporary disadvantage as compared with those of a neighboring State which did not require these precautions.

Since we must have timber it is clear that

Munn & Co., Inc., 361 Broadway, New York

The purpose of this journal is to record accurately and in simple terms, the world's progress in scientific knowledge and industrial achievement. It seeks to present this information in a form so readable and readily understood, as to set forth and emphasize the inherent charm and fascination of science.

The Sin of National Improvidence

AMONG the many questions of national significance which have recently been brought to the public attention, there are few which compare in importance with that of conservation.

Not many thoughtful Americans will deny that extravagance is one of our distinctive national faults. At the first thought it may seem strange that the nation which has sprung from the thrifty settlers who founded Plymouth and Jamestown and were schooled in the rough adversities of an unusually strenuous pioneer life should have developed that very improvidence which the circumstances surrounding the life of the early settlers strictly forbade. Not alone in the beginnings of the nation, but for many a decade of its early existence, the conditions of life were exceedingly hard. Never surely did a race of men so literally earn its bread by the sweat of its brow as those resolute pioneers who had to coax the means of life from the rock encumbered hills and valleys of New England or endure the prodigious toil of clearing away primeval forests before they could lay bare a patch of arable land from which to raise the food and feed for man and beast.

It was in later years when the van of pioneer conquest had been pushed out into the rich and unobstructed prairie lands of the West that the American people began to realize with what lavish abundance nature stood ready to pour forth her treasures. When the cattle multiplied upon a thousand hills and the crops burst forth in luxurious abundance from the virgin soil, the pressing need for careful husbandry of resources was no longer felt. Hence it has come about that nature herself is largely responsible for that later extravagance which led the American people to squander resources which they have come to regard and speak of as practically inexhaustible.

Unfortunately the habits learned on the farm have been carried into those great industrial activities whose magnitude is one of the wonders of our modern life. If the riches of the soil were inexhaustible so also seemed to be those of the forest of the mine and of the rivers and lakes and seas with their teeming millions. Hence it has come about that in our effort to gather only the riches which are immediately and easily accessible we have been using up nature's storehouse of raw material ruthlessly destroying or letting go to waste thousands of square miles of forest and millions of tons of coal and precious minerals. Year after year crops have been sown upon the once virgin lands until in sheer exhaustion they have refused to render the plenteous yield of former years or even to yield any crops whatsoever—at least until the husbandman shall have restored some portion of those nutritive elements which are necessary to germination, growth and full fruition.

We have all heard and read a great deal during the past few years about this subject of conservation but it is a question whether many people have any just conception of how great has been the wicked waste of the past and how pressing is the need for future economy. The present issue of the SCIENTIFIC AMERICAN is published in the hope that it may put this whole question in its true light and show exactly what are the present conditions and what are the methods which have been pursued by the Federal Government in the effort to repair the damage which has been done, and properly conserve those natural resources upon which not only the prosperity, but the very life of the nation depends. The articles are written by men who, because of their position at the heads of the several departments which are devoted to conservation, are possessed of a full knowledge of the facts and are qualified to state the case with authority. The conservation number is issued in the belief that it will not only answer a thousand questions which have arisen in the mind of the American public, but will also make clear the necessity for a most earnest and intelligent co-operation with the government in this great national work.

The Hand That Wrecks the Cradle

IN a recent editorial in these columns, we spoke of the work which the modern eugenist is doing to arouse the public conscience not only to the possibilities of improving the human race by proper selection of parent types, but to the far more vital matter of mere self preservation. We called attention to Pearson's statement that 25 per cent of the present generation is producing 50 per cent of the next, that imbeciles, paupers, criminals and defectives were reproducing faster than manufacturers, merchants, lawyers and physicians, that, in a word, if the present form of society is to continue, something must be done to prevent the perpetuation of defective classes. To those readers who may take more than a casual interest in the subject, we commend the reading of Prof. William E. Kellicott's Social Direction of Human Evolution, a book which presents in a popular and yet authoritative manner the dangers that beset society.

That these dangers are not mere dreams, that heredity does play the major part in the prevention of desirable and undesirable classes alike, is only too easily demonstrated in order to drive home the necessity of a careful study of human heredity. We have only to cite Poellmann's study of a family established by two daughters of a woman drunkard, who in five or six generations produced all told 834 descendants of whom over 700 were professional beggars, inmates of almshouses, criminals and incompetents of various degrees, and to contrast with that degenerate family the 1,394 descendants of Jonathan Edwards, most of whom occupied distinguished positions in educational institutions, in the diplomatic service, in political life, in commercial affairs, and in literature.

Environment plays but a small part in this process of conscious race improvement. Free public libraries, clean houses, modern sanitation cannot correct bad blood. Slums, sweatshops and dirt are bad, not because they breed criminals but because they may kill off classes which, if nourished, might become strong and healthy stocks. What is wanted is a more painstaking and scientific study of the germ plasm that develops a healthy or unhealthy strain, rather than more asylums and prisons for the correction and punishment of offenders. A philanthropist who will wisely donate to that cause the funds which would otherwise find their way to the coffers of charitable institutions should earn everlasting fame. Greater than any political issue greater than the building of more universities and libraries, greater even than the abolition of standing armies is any movement which has for its object the direct improvement of the human race.

The sociologist has had his day. His statistics of people who are ill fed and ill housed, can serve no other purpose than that of indicating the need of better accommodations for the poorer classes in the effort to uplift them. It is to the biologist to whom society must turn—the man who can definitely point out why this or that strain is undesirable, why this family should not be married into, because of its questionable ancestry, why that stock is desirable because from it there had sprung men and women of genius.

Able work in this direction is now being done in England under the guidance of Prof. Karl Pearson of the Eugenics Laboratory of the University of London, and in America by the Committee on Eugenics of the American Breeders Association, of Cold Spring Harbor, New York. Only a beginning has been made, but a beginning that has shown that behind the phrase "race suicide" which was bandied about a few years ago, there looms a danger far greater than most of us realize. It is becoming increasingly evident that good blood means not simply descent from an aristocratic race, but descent from a race physically and mentally and morally strong.

When we consider that, according to the latest available census reports, there are among our 90,000,000 people at least 200,000 who are insane and feeble minded, 100,000 who are blind, 100,000 who are blind and deaf and dumb; 80,000 who are paupers in institutions, two-thirds of whom have children physically or mentally deficient, 100,000 prisoners, several hundred thousand more who ought to be prisoners, 25,000 juvenile delinquents in institutions, and 2,000,000 who are in hospitals, dispensaries, and homes of various kinds, and lastly when we consider that this rough total of nearly 3,000,000 defectives is capable of transmitting its tainted protoplasm to the next generation, there is indeed room for the new science of race improvement, and room, too above every asylum and prison portal, for Rentoul's epigrammatic utterance:

The hand that wrecks the cradle wrecks the nation.

A Chemical Solution of the Potash Problem

IT is a most humiliating fact that America must buy all her potassium salts from Germany—humiliating because they are absolutely necessary in renewing the fertility of our soils. Our farmers paid the Fatherland $8,000,000 last year for this one element, importing 160,000 tons of potassium chloride as well as large quantities of potassium sulphate.

Germany is very fortunate in possessing the wonderful Stassfurt deposits of mixed salts, for she has practically a monopoly of the potassium market of the world. Their government has recently given official sanction to an effort of a German trust to put up the price, although the stuff is cheaply mined. Here in America we have enormous deposits of phosphate rock and from various sources such as stockyards, Chili saltpeter, the air, etc., are assured unlimited nitrogen, but our crops demand, in addition to phosphorus and nitrogen, the third element potassium. In spite of the fact that we send $8,000,000 a year out of the country for potassium, we have enormous quantities of it at home in feldspar rock. The slow weathering of this rock makes some of it available for plant use in soluble form, and our unfertilized soils owe much to this fact. Heavy cropping, however, removes this necessary element faster than Nature prepares it in suitable form for plant use, and so arises the need of fertilizer to make good the loss.

The facts we must face then are these. Potassium chloride is quickly taken up by crops, but feldspar is too slowly available to maintain the fertility of the soil. Therefore our American problem is to make potassium chloride from our abundant feldspar by chemical means. When that is done cheaply we may snap our fingers at Germany for we will have all our plant food at home. Even if such a process could not quite compete with the German salts at present prices the fact that we were prepared if needs must, to make our own potassium chloride would be a wholesome restraint on exorbitant price raising. It is encouraging to every patriot to learn that the chemistry of this much-desired process has been fairly well developed. By heating finely ground feldspar with calcium chloride (a cheap by product of soda making) and some limestone the potassium can be extracted as the soluble potassium chloride. The residue is suitable material to calcine further into cement. The cost at present is much too high, but the sale of the cement would reduce this. One ton of feldspar rock may yield 190 pounds of potassium chloride worth $4.50 and five or six barrels of cement worth as much more. In making our annual allowance for this fertilizer we would throw on the market 7,000,000 barrels of cement—at present we use 65,000,000.

The experts of the Tariff Board urge the appointment of a national commission of chemists, geologists, engineers and business men to work out the problem on a scientific and economic basis. There is more to it than chemistry alone. Not the least factor is the location of raw materials and transportation difficulties. We owe it to our economic independence to attack this question, not from individual business motives, but from motives of the purest patriotism.

Science for Its Own Sake

SIR JAMES DEWAR recently pointed out that the whole cost of a century's research of experiments at the Royal Institution has been only about $600,000. What an insignificant sum to pay for the benefits mankind had received from the splendid investigations of Young, Davy, Faraday, Tyndall, Dewar himself, and others, comments the London *Times*. Yet most of the labors of these men were carried out *honoris causa*, and not for immediate material benefit.

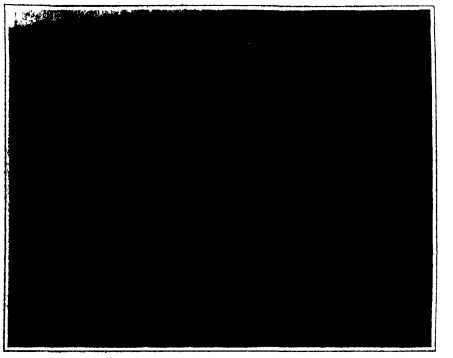
(Concluded from page 148.)

the duty to surround the industry of growing wood with such conditions as will make it attractive rests squarely upon the people of the United States. The penalty for shirking this duty is a famine of one of the three great raw materials: coal, iron, and wood.

The people, then, have obviously shirked some part of their duty by failing to make forestry easily practicable. The lumbermen of the United States, it is true, have received from the government more practical help toward the introduction of forestry than has ever been offered to the lumbermen of any other country. Information of all kinds, co-operation, and practical examples have all been supplied plentifully and well. The United States Forest Service has given encouragement and assistance to the lumber fraternity to a degree wholly without example in any other country.

As a nation, we have neglected to provide the conditions necessary for all this help to have its most useful effect, and the conditions for practical forestry created under our laws leave much to be desired. Still the government has been most generous to the lumbermen in very many respects. Thus under the land laws, which have been bad, and their administration, which has been worse, the lumbermen have acquired timber land very easily, and a great concentration of timber ownership has been allowed to grow up. According to the official figures of the Commissioner of Corporations one hundred and ninety-five owners now control forty per cent of the standing timber of the United States. Three corporations, the Weyerhaeuser Timber Company, the Southern Pacific Company, and the Northern Pacific Railway Company, with their subsidiary companies, have nearly eleven per cent of all our privately owned forests. Less than half a century ago, the government owned not less than three-fourths of the standing timber in the United States. To-day, only one-fifth of all standing timber is publicly owned, while four-fifths have passed into private ownership, together with the land upon which this timber stands.

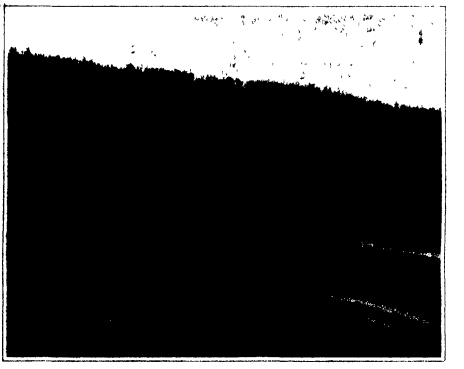
The men who hold this land own it in fee simple. It is useless to expect that they will handle it in such a way as to reduce the amount of concentration. The whole trend of our commercial development is toward great combinations of property in all the fields of industry. It is worse than useless to imagine that the old days of unrestricted competition can be restored by any legal devices whatsoever, even if it were desirable to do so. The remedy for evils of this kind is not unrestricted competition, which it is perfectly obvious can never return, but government control and regulation of combinations, concentrations, and monopolies. Forestry is of such a nature that unrestricted competition between the owners of timber lands leads not to forest protection but to destruction and waste. Of all concentrations which exist, there is none in which government regulation is more essentially and immediately necessary than in the concentration of standing timber.



Of late years lumbermen and foresters have been most friendly. The foresters have been listened to, encouraged, and assisted by the lumbermen, whose response to the foresters has been in many ways most gratifying. They have done everything that could have been expected of them, except to practise forestry. They profess themselves desirous of doing so. It is of the first importance to the nation that they should, and the time to begin is at once.

The great interstate concentration of timber land ownership has made clear the duty of the nation to interfere for the protection of the legitimate interests of us all, lumbermen included. Since the nation owns but a small fraction of the standing timber, and since the wise handling of all of that timber is essential for the future welfare of the country, there remains nothing for the people to do but to accept the situation and regulate the handling of private forest land.

There is nothing revolutionary in such a doctrine. The Swiss, a people far more democratic than ourselves, have long ago adopted it, and the Federal Government protects and regulates the forests necessary for the general welfare. In the Republic of France, this doctrine is one of the fundamental conceptions of government. There is obviously no more reason why an individual in the United States should be allowed to handle his own forests in a way to injure the public welfare than why he should be allowed to use his own property in a city so as to endanger the public health.

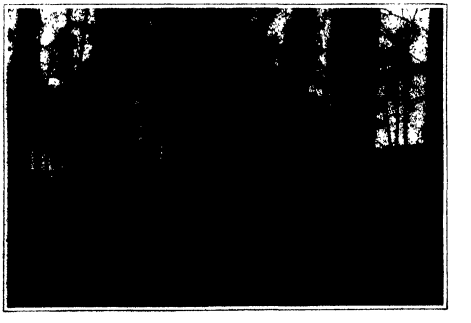


I am far from having any quarrel with the fullest exercise of State sovereignty over the forests within the boundaries of each State. But the problem of the forests, like the problem of the streams, is by its very nature an interstate affair. It may take long to work it out, but before we are through with it the regulation of the lumber industry in the interest of the public welfare must be and will be accomplished mainly by the nation itself.

There are then two principal things to be done. First, the States and the nation must improve the conditions which now surround and retard the practice of forestry by private owners. Second, the destruction of our forests by the private owners of timber lands must be stopped. I anticipate with confidence that the lumbermen will give their powerful help in the task, but whether they do or not, the problem is far larger than anything except the nation itself, and the general welfare must control.

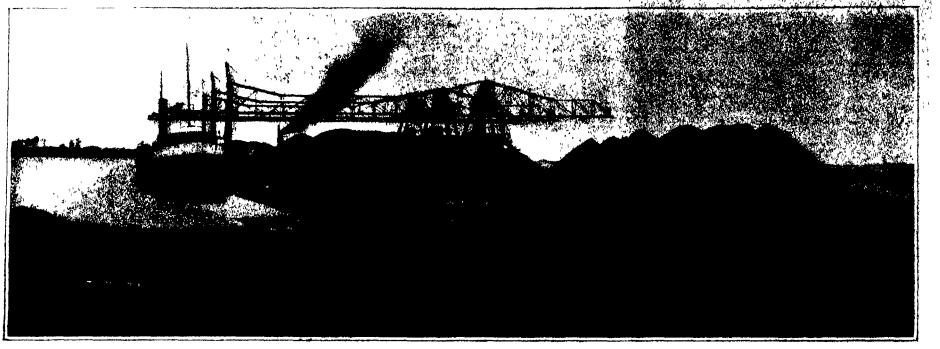
Trails and telephone lines are essential to protection of forests from fire.

AIDS TO FIRE PATROL



The denuded lands are privately owned, and have been logged under ordinary methods. The upper slope is on a national forest, and has been logged conservatively.

NATIONAL AND PRIVATE OWNERSHIP



Young growth coming in on old burn was in a national forest and protected from fire.

THE RETURN OF THE FOREST

This forest has been cut without injury to young trees, left standing, which will produce good second crop.

A FACTORY OF WOOD

Unloading coal at a lake port.

The Use and the Waste of Our Coal Supply

At the Present Rate Coal may be Exhausted while the Nation is Yet Young

By Dr. Joseph A. Holmes, Director of the Bureau of Mines

THE habit of waste is one of the unfortunate inheritances of the 20th century American citizen. It is our most serious hinderance to the development of both individual and national efficiency. More than anything else, it stands in the way of the wise use or conservation of the resources, ample, present and future, supplies of which are essential to our individual and national welfare.

This fact is important enough to command attention when applied to products of the soil of which we have new supplies each year, or to our forests of which each century may bring returns, or to the soils themselves to which the underlying rocks slowly yield new additions as by careless culture we permit the fertile surface to be eroded and carried off to the sea. It is still more important when applied to our mineral resources, of which we have but the one supply—which supply has required millions of years for its accumulation, and which supply at the present increasing rate of consumption may be exhausted while the nation is yet young, and especially when applied to our fuel resources of which the portions used each day are completely destroyed.

And, yet, the very abundance, and supposed abundance, of our mineral resources has developed and encouraged the habit of waste. A legislator of many years' experience in national affairs, was recently quoted as saying in a public address: "Why, worry ourselves about a future coal supply when there is undiscovered coal enough in the Rocky Mountain regions to warm this nation for an indefinite future." Another of our "older statesmen" has in recent public utterance voiced the same view: "We have enough coal and to spare," he said, "for a thousand decades of our national history; therefore, we need not concern ourselves about the age, nor the waste of American fuel." And the average citizen has so long heard so much about the "exhaustless resources" of this country, that he is half way inclined to believe such statements.

It is only within the past few years that the real facts of the situation have impressed themselves upon us. The end of the coal supply in certain important centers is found to be already nearly in sight. The cold-blooded statistician studying the future in the light of the past, tells us that, if the increasing rate of consumption of the past century be continued in the future, our national coal supply may be exhausted within less than two hundred years. The States that first feel the effect of this fuel exhaustion, in spite of their larger supplies, will be those like Pennsylvania, West Virginia, Ohio, Illinois, and Iowa, located near great manufacturing and transportation centers, and upon whose supplies the largest drains are being made—both in the use and the waste of essential resources.

Be this all as it may, as to one fact and principle all thoughtful citizens must agree, namely, that while no one questions the right of each generation to use efficiently of this coal supply all it really needs, this right carries with it a sacred obligation—that no man and no generation of men shall waste that which is not needed for its actual use, and which, therefore, belongs to the nation.

Waste in Mining Coal.

The fact that the loss of coal in mining operations now approximates 250,000,000 tons per annum; or that we leave underground in such condition as to make its future recovery impracticable, half a ton for every

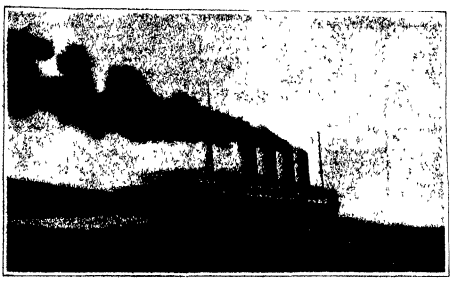
Removing coal from hold of lake steamer to a storage platform.

...mined coal, prior to its reaching the surface, is a fact that ...mands careful consideration. And what makes ...s still more serious is the fact that this coal left ...derground is often a menace to property by origin...ting or harboring mine fires, and often a menace to life by developing surplus of explosive mine gases that may by falls or settling of roof be driven unexpectedly into the working parts of the mine, where open lights or other agencies may ignite it and cause a mine disaster.

In some mines from sixty to ninety per cent of the coal is brought to the surface. In many mines the recovery ranges from sixty to seventy-five per cent of the whole, while in some mines the recovery is from forty to sixty per cent. In some cases this loss consists mainly of the pillar coal left in place to support the roof while the other coal is being removed, and which pillar coal may be later not removed or only partially removed

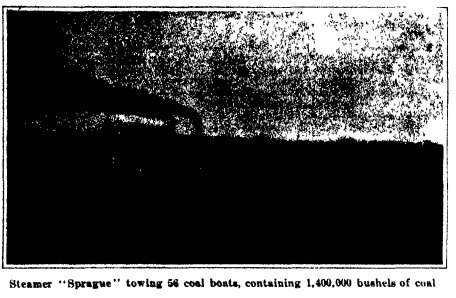
In addition to this pillar coal in many mines there is a "roof coal or "rooster coal," or "top coal and also a "bottom coal, which is also left underground because lower in quality or more expensive to mine

Additional losses of coal coming from the pulverizing action of the drills and coal cutting machines (see photo) from the grinding of coal under the wheels of the mine cars (see photo), and from the sorting or screening and washing and general handling about the shaft and tipple Much of the fine coal in the mines is not removed and remains as a menace to life if involved in dust explosions Much of the fine coal removed from the mines accumulates in the great black piles of *culm* where it may or may not burn from spontaneous fires, or it may be shipped away and marketed as slack or in a few cases this fine coal is being briquetted and sold at prices as high as those obtained for the best lump coal



All the above sources of waste relate to the losses in mining a single bed of coal Still other losses come where several beds of coal occur one above the other with thin intervening beds of rock from the prior mining of the lower bed This often results in an irregular breaking and settling of the overlying bed or beds of coal in such a manner as to seriously interfere with the subsequent mining and recovery of this overlying or upper coal

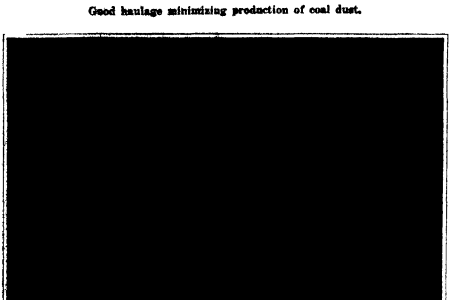
In other countries regulations require in such cases the prior mining of the overlying or upper beds of coal in order to avoid this unnecessary settling and breakage of successive higher beds But in the United States each company has followed the law of "present profits and least resistance and the 'future welfare of the nation has remained an irridescent dream



Losses in the Transportation of Coal.

From the shaft and the tipple the coal falls into the forty or fifty ton coal cars for transportation by rail (see photo) or into the barges for transportation by river (see photo) In these transport barges, as seen on the Ohio and Mississippi rivers, a single small stern-wheel steamer attached at the rear of the group of the barges, may carry to New Orleans from 40,000 to 60,000 tons of coal (photo)

If intended for ocean or lake transportation by steamer, the coal may be allowed to run from the opening in the bottom of the car (or an elevated track) directly into the hold of the steamer; or each car may be elevated separately and inverted, the coal rushing down the chute into the steamer's hold. At the other terminal port the coal whether transported by barge or steamer is lifted by great steel grab buckets and placed on storage platforms (see photo), or again placed on cars for further transport (see photo) At every handling of the coal there is an increase of fine coal or slack (photo), and a small per cent of loss But often the total actual waste in the haulage, including the several transfers, will aggregate less than 10 to 15 per cent of the original tonnage, and while the fine or slack coal sells at prices from 20 to 50 per cent lower than the good lump coal, with modern automatic stokers and briquetting plants, there is really little loss in actual heating value



This ship consumes 1050 tons of coal each day

Steamer "Sprague" towing 56 coal boats, containing 1,400,000 bushels of coal

Good haulage minimizing production of coal dust.

Undercutting coal with compressed air drill.

THE USE AND WASTE OF OUR COAL SUPPLY

Losses in the Use of Coal

Great as are the losses of coal in mining they are proportionately less than in its burning in the furnace of the country The experienced manufacturer who as a large consumer of coal habitually watches the double entries on the pages of his ledger for profits and losses does not hesitate to express his surprise and disapproval when he hears the story of mining losses approximately 250 000 000 tons of coal in a single year but in doing this he often loses sight of the no less serious fact—that of the coal used in his own furnaces *less than 10 per cent of its heat units are converted into mechanical work* in his factories or the larger fact that of the 400 000 000 tons of coal probably used in the power plants of the country (including locomotives) 270 000 000 * or 90 per cent of the whole was lost in the several transformations of energy and not more than 10 per cent of the heat units or the equivalent of only 30 000 000 tons of this coal was transformed into the mechanical work of the nation

The situation seems clearer if these losses are subdivided or classified This cannot be done accurately in a general statement because of the variations in the different furnaces boilers and engines But taking a common type of smaller power plant the disposition or consumption of British thermal units in the burning of the ordinary bituminous coal containing 13 500 B T U has been given as follows

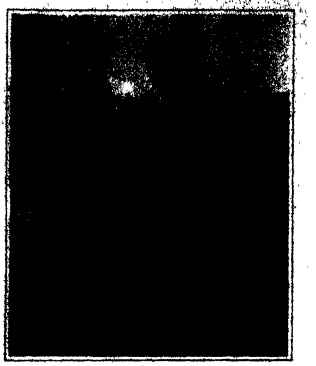
	B T U	Per cent
Loss in ashes	135	1 00
Carried off in gases	2 970	22 00
Loss in radiation from boilers	675	5 00
Carried off in auxiliary exhaust	190	1 41
Loss in radiation and leakage main pipes	210	1 56
Loss in radiation from small pipes	30	0 22
Loss in radiation from engine	280	07
Rejected to condenser	7707	57 11
Converted to power or mechanical work	1 277	9 43
	13 500	100 00

The government of the United States is probably the world's largest owner of coal lands it also operates a large number and variety of heating and power plants located in widely separated parts of the country besides the Panama railroad lines of transport steamers and its naval vessels Furthermore the fuel problem enters so largely into the manufacturing transportation and interstate commerce of the whole country that they may be reasonably classed as national problems

In recognition of these facts Congress several years ago authorized an investigation of fuel problems first under the Geological Survey and subsequently under the Bureau of Mines Under the latter bureau this work is now being reorganized and cooperating with other existing agencies the engineers and chemists of the Bureau of Mines working at its Pittsburg laboratories are endeavoring to locate and reduce or eliminate as far as may be possible the sources of loss or waste not only in the mining but also in the use of our fuel resources

(continued on page 141)

* this does not include loss which is extremely variable per cent of the coal which is distilled in making coke and passes through the gas fires in an unburned condition along with the ashes



A truck with a stone-dumping body.

The Versatile Motor Truck

Novel Designs and what They Accomplish in the Economical Handling of Material

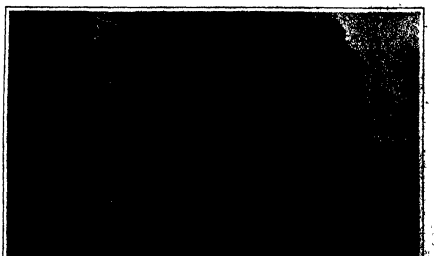
By Harry W. Perry

A truck used as a hoist.

BECAUSE the motor truck is a work machine, it is relatively ponderous and slow, but what it lacks in speed and grace of design is more than made up in the spectacular nature of its varied activities. It does not make such a direct personal appeal as the pleasure car, since not many look upon the business vehicle now as a machine from which any personal pleasure or direct benefit can be derived. When, however, the mind dissociates from the mention of commercial motor vehicles the thought of mere substitutes for horse-drawn trucks and delivery wagons, it will become evident that the term embraces a great variety of types—all, in fact, that are not classed as private pleasure cars. While motor trucks are business vehicles, they are not necessarily prosaic.

In due time more interest will be shown in so-called commercial motor vehicles than in private pleasure cars. The masses in the cities will come to realize that they have as direct a concern in motor omnibuses, taxicabs, sightseeing cars and the varied types of municipal vehicles and cars for Federal purposes as they have in runabouts, touring cars and limousines. In the self-propelled fire apparatus with which all progressive cities will be supplied in a few years, the people will see the instruments of thrilling rescues of human lives and property. In motor patrol wagons they will see the means for prompt quelling of riots and removal of dangerous and disorderly persons; in motor ambulances the vehicle for relieving human, equine and canine suffering, in the motor mail wagon the mechanism for hastening communication.

When we consider the conditions that will prevail when these types of power vehicles and the great variety of other forms for industrial and mercantile purposes have been generally adopted, and when we shall have an opportunity of comparing the clean, smoothly-paved streets, the freedom from flies and germ-carrying dust, absence of the noise of pounding horse hoofs and steel tires, reduction of traffic congestion and the elimination of the harrowing sight of horses prostrated by midsummer heat or crippled by winter's ice pavements with conditions that prevail now, every thinking person will be impressed with the idea that the pleasure car with which the civilized world has been obsessed for more than half a decade is, after all, a relatively small factor in a revolutionary change in a method of transportation almost as ancient as the human race, and that this change touches the life and has a direct bearing upon the well-being of every individual in the city.



Aside from the striking nature of public services in which motor vehicles are engaged, there are many applications of the machines to private enterprise that are most interesting. All sorts of work, from thawing frozen water pipes in an emergency, to drawing plows in the farm fields, come within their scope of utility. At least 125 distinct lines of trade are using the trucks built by a single big manufacturing company that produces only machines of three tons capacity. It is natural, of course, that the motor truck should have been adopted more generally by the lines of business that found the horse least capable of doing the work required, either because of its difficult nature or because of long distances to be covered in a short time and long hours of service that would seriously fatigue the best animals.

A tilting body operated by means of a hand winch and rollers. This operation does not require any greater physical exertion than the cranking of an ordinary gasoline motor.

A motor truck carrying not only its own load but hauling an ordinary truck as well.

A truck unloading boards. The driver sits in a cab which completely protects him from wind and weather.

Just to cite one kind of work that is beyond the capability of horses to do successfully, it will be remembered perhaps that early last spring several sixty-ton steel girders for the new Municipal Building in New York were hauled from the river front, near the Battery, to the location of the building at the Manhattan end of Brooklyn Bridge. Thirty-six horses, hitched in an almost unmanageable string of eighteen teams, were used for draft purposes, and because of the interruption of traffic and confusion that would have been caused in the metropolitan streets of such an outfit during business hours, the girders were hauled during the night and on Sunday. In their passage numerous iron manhole covers were crushed in and considerable damage was done to the street paving. It is not difficult to imagine the vociferous bedlam that accompanied the movement of the teams and the noise made by one hundred and forty-four iron-shod hoofs, and the almost insurmountable difficulty of making the long string of horses pull in unison, and of turning corners successfully. A five-ton electric truck used for the same purpose in another city moved with ease a trailer weighing five tons and loaded with a steel girder which alone weighed twenty-six tons.

One of the most exacting branches of transportation work is that of the big express companies, which receive and send their shipments by fast passenger train and must perforce conform to railroad schedules. All of these companies use some motor wagons, and one in particular, which has used steam, gasoline and electric power wagons continuously for the last eighteen or twenty years, now does the major part of its transfer and delivery work with electric wagons in the principal Eastern cities. The gasoline trucks owned by another of the national express companies are operated on a time schedule as exact as the railroad time sheet, and are kept in service twenty hours out of twenty-four, with a double shift of drivers.

Delivery work for department and dry goods stores calls for the covering of routes too long to be successfully served by horses. One New York store has a route of more than sixty miles that is covered daily by one motor wagon and one driver, with an average of about one hundred stops for delivery of parcels. Horses, of course, could not be used in this case, for even if two changes of teams were made in the day, the speed could not be maintained. Some big department stores make their long hauls into outlying residential sections at night, and make their local deliveries the next day from distributing depots. In this way one big house keeps its heavy trucks running twenty-two hours a day, except on Sundays, when they are given a thorough inspection, cleaning and adjusting. A trip on one of these department store or express trucks in the middle of the night would prove quite as novel and interesting as a night run of the same duration in a touring car under ordinary circumstances.

Coal, beer, lumber and machinery trades and many lines of heavy manufacturing whose hauling is hard on horseflesh have adopted the motor truck freely and are getting excellent service from the machine. Peculiar conditions that obtain in some of these businesses have resulted in the development of special quick loading and unloading methods whereby the vehicle can be kept on the move during the maximum number of hours daily, thereby realizing the principal advantage that it possesses in superior speed and endurance over horses. Coal dealers order their power trucks fitted with bodies which are provided with chutes, and which can be raised above the frame of the chassis at a sharp angle so that they will empty their loads of from three to ten tons by gravity in from five to fifteen minutes, with little or no shoveling. Contractors are becoming frequent purchasers of motor trucks fitted with dumping bodies that can be discharged of their loads sometimes in less than a minute. Most of the dump trucks so far built are tipped by the manual turning of a crank, but several have been built to order that are equipped with power-operated tipping mechanism. One of these is a seven-ton gasoline truck that is often used for hauling hot asphalt. This material has a tendency to stick, and consequently the body had to be constructed to tip to an angle of forty-five degrees. It takes only forty seconds to elevate this body with power from the engine and discharge the seven-ton load.

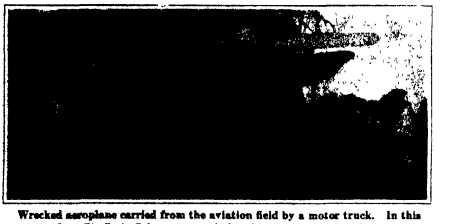
Ingenious quick loading and unloading methods have been developed by the lumber trade whereby a motor truck can take on a load of three to seven tons of lumber as a unit in a few minutes, the turning of windlasses by hand serving to roll or slide the load from a horse truck upon the power vehicle, which then leaves the yards to deliver it. The horse trucks are driven to the different lumber piles to be hand loaded, and thence to the wagon shed to await the motor truck, a single team of horses sufficing for about a score of such wagons. The loads can be discharged from the power trucks by releasing ropes or chains at the rear end and allowing the lumber to roll back by gravity or by rolling the load back by turning the cranks on the rear end rollers until the ends of the boards drop to the ground. Then the truck is driven out from under the forward end of the load.

A leading department store in New York and another in Pittsburg operate eight or more three-ton trucks each that are especially arranged for quick loading and unloading. Light bodies of crate construction are built to fit inside the regular covered bodies. When a truck arrives at the store this inner body is withdrawn upon a hand truck to the rear, and on this is taken to any floor in the store by means of a freight elevator to be loaded. A duplicate crate that is waiting ready loaded to put its predecessor in place is then run out on the hand truck, and the truck starts off with it. The reverse process occurs at the other end of the truck's route. In a record load for one of these trucks at Christmas time were 3,000 parcels. Ordinarily the proper loading of the packages requires from one to three hours, so that the system enables the truck to make two or three times as much mileage as would be possible if it had to stand idle while undergoing the ordinary loading and unloading processes. The average daily mileage of seven of these trucks used during a fifteen-month period in New York was seventy-two miles each, counting twenty-six working days to the month. Several of the machines averaged one hundred and ten miles a day for months at a time.

The combination of vehicle and power plant that constitutes the motor truck renders the machine available for many classes of work heretofore done by hand and by portable or stationary engines. In fact, it is a self-moving portable power plant. In its most common form as such it is fitted with a winch or windlass, usually under or just back of the seat, which is turned by power from the vehicle. The winch may be gear driven from the engine of a gasoline machine, or turned by a small independent electric motor supplied with current from the battery of an electric truck. In either case the winch can be used for a variety of purposes. Both types of trucks are used by a large safe manufacturing company which utilizes the power winches for loading the safes on the platform of the truck by drawing them up a pair of skids and also for hoisting the safes to and lowering them from windows of any floor in tall office buildings. This method has the advantages of being quick, safe and cheaper than the old way of having a gang of workmen turn a hand windlass. Fewer men are needed, passersby on the walk and traffic in the street are inconvenienced for a shorter time, and customers of the company are better satisfied by the briefer interruption of their office work.

A few years ago all telephone, telegraph and electric light and power wires that were placed in underground conduits were drawn into place by gangs of laborers who turned huge wooden capstans that had to be set up in the street anchored in position by iron pegs driven in the pavement and moved from block to block on wooden rollers which were taken from behind and put in front as the capstan moved along for the next successive step in the work. Compare this primitive procedure with the present-day way, in which cables of wires are drawn into place under the street by power winches on heavy five-ton motor trucks. In New York one electric light and power company uses half a dozen such trucks for this purpose, and also for the more spectacular work of erecting the heavy ornamental cast iron electric light poles used for city lighting. These poles are thirty feet long, and are much too heavy to be set up by laborers without a derrick. But the truck, with its power winch, makes easy work of the task.

By way of an aside, it is pertinent to observe right here as an indication of the trend toward the horseless condition that is predicted for large cities in the near future, that the New York Edison Company has abandoned altogether the use of horses in Manhattan and a large part of the Bronx, and employs instead a "fleet" of eighty electric trucks and delivery wagons. Within the next five years, and probably sooner, it will get rid of all its remaining animals, as will also the New York City Fire Department, some of the express companies and many retail houses in the metropolis, some of which are now operating from forty to nearly one hundred motor delivery wagons.



In addition to the ways already mentioned, the power plants of motor trucks are used in an auxiliary way for pumping water out of manholes in the streets of cities.

Conservation of Oil and Natural Gas

Economies in Field, Factory and Home

By Dr David T Day, United States Geological Survey

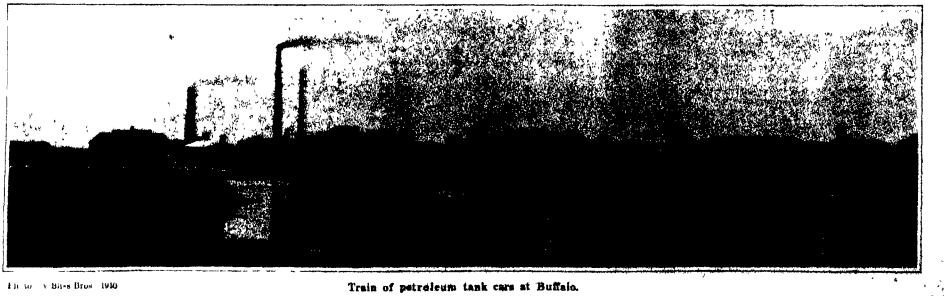
IN regard to conservation of our natural mineral resources the petroleum industry affords a better example of what can be accomplished in useful application and preventing of waste rather than an illustration of deplorable waste which has been the theme of most that has been written on this subject for other industries

Nevertheless the petroleum industry is one of the most vital cases for exercising every possible care in the utilization of a limited amount of material The gloomy outlook for the United States without great care in utilizing the stores of petroleum and other fuels is well illustrated by the present condition of Italy For in spite of a climate unrivalled for the growth of plants and with men and women strong and skillful in the arts of agriculture the peasants are proverbially poor Only a few days ago in looking at an Italian photograph of an unusually strong woman carrying on her head a large bundle of firewood I was puzzled to explain how poverty was consistent with this magnificent physical development and yet the picture carried in it the obvious reason The world has moved past the stage when human power is sufficient in daily labor Aid must be had from power from a large supply of cheap fuel in addition to the energy to be contributed by human labor and only the countries prosper where such fuel is abundant Italy's fuel supply has burned out unless they harness the exhalation from Mt Vesuvius Even the wood which the woman in the picture was carrying is scarce and costly and in no way sufficient for the development of enough energy for efficient manufacture

Contrast this condition with the United States We have a supply of at least 10 billion barrels of petroleum in what we already know of the resources of the United States From these vast resources we produced last year over 200 000 000 barrels of oil In addition we produced natural gas to a value of at least $1 000 000 In other words leaving out of consideration copper and iron the oil and gas of the United States was worth more than the gold silver, lead and every other metal product produced in the same length of time It is important to emphasize the fact that we do not need this great production But there is no possible method of preventing the producers of oil from taking it from the earth as rapidly as possible when they either own the oil lands or own leases on the oil lands and there is no way of curbing the haste with which the oil is pumped out by one producer lest his neighbor will secure the greater part by prompter action The ability of the owners of any large tract of oil land such as the people as owners of the oil on the public domain or of any large oil company with a large tract of developed oil land to withhold development on these large tracts is admitted but aside from this the human oil fields will be developed as rapidly as human enterprise can put the product above ground

Intelligent utilization of oil therefore has had to face extreme conditions of sudden floods of oil and in general more oil than was needed These exceptionally trying conditions have been met with a significant success It is very much easier to record the failures to conserve rather than the nearly uniform success When the Lucas gusher broke loose near Beaumont Texas the oil was lost for lack of tankage for a few days and fire added to the waste In the opening days of the Glenn pool in Oklahoma oil ran to waste down the creek and in California the first flows of the Silver Tip the Lakeview and other gushers have been lost but the total loss from all these sources is trifling

This is an achievement which calls for great congratulation rather than the criticism of methods which has been found necessary in considering the conservation of coal and the shameful devastation of our forests Perhaps it will be useful to discuss how this careful saving of petroleum has been brought about as a means of inspiring similar enterprise in other industries



Oil conservation goes back beyond all the oil companies great and small and begins with Samuel Kier a merchant of Pittsburg who was also from necessity, an inventor or better still an adapter, of a lamp for burning oil He added a chimney which made the oil burn with a bright light This supplied a market which did not before exist and which has spread from Pittsburg to remotest China A C Ferris came next with his genius for oil traffic He began the process of exporting oil from Pittsburg to the ends of the earth From that day to this business sagacity has dominated oil

Pipe Lines—It was the spur of business competition that developed the *pipe line* at first facing hostility and actual violence from the army of teamsters in order to get the oil from the well mouth to a railroad or river landing and finally invoking engineering skill the *oil* men emancipated *themselves* from railroads and pumped oil over the Alleghenies to tide water Pipe line efficiency has been perfected in both directions—toward the consumer and toward the producer The refineries have tended to accumulate near the coast because it was evidently cheaper to transport the oil in the crude condition as far toward the consumer as possible and only to resort to costlier transportation methods when it became necessary to convert the oil into the products to be consumed each of which must be distributed by its own system

The pipe lines have increased in number and economy has been promoted by the best types of pumping equipment In fact pumping engines have been greatly developed for all purposes by the demand for them afforded in transporting oil

Meantime the branch or 'gathering' lines have crept outward as the oil pools increased until there are now many miles of pipe lines in the United States Of greatest help however has been the system by which the pipe line has always been extended to the well mouth *promptly* when new fields have been discovered The only burden for the oil producer has been the development of his oil pool It has become axiomatic that the oil is as good as sold as soon as it is produced

Uses of Crude Oil—It is evident that the requirements of the moment must be considered in the uses

Underwood & Bliss Bros 1916

Train of petroleum tank cars at Buffalo.

for oil, and not the ideal utilization based upon the highest grade products that the oil can be made to yield. In fact the sudden floods of crude oil have made it necessary to get rid of the oil for any purpose whatever, so long as the oil is consumed. Of the entire supply, the greater part has been distilled and refined so as to yield the greatest amount of lamp oil of satisfactory quality and the minimum of by-products such as gasoline, paraffine wax, lubricating oil, and coke products. Usually there has been a steady market for lamp oils at home and abroad. Within the past few years this policy has of course greatly changed, due to the increased demand for gasoline, and due also to the over supply of kerosene. The consumption of kerosene has not declined. It has increased, but not so rapidly as the production of crude oil.

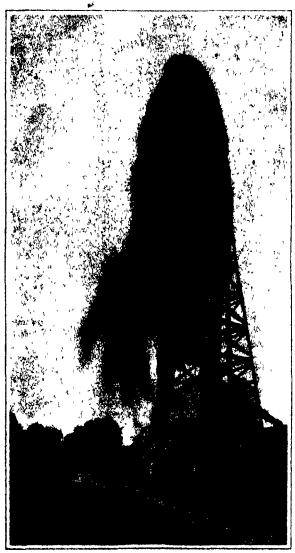
Fuel Oils.—This necessity of forcing a market for crude oil has developed uses which might long have lain dormant. Chief among these is fuel oil, second, and always increasing, is road oil. Luckily the recent great finds in Texas and California have been very suitable for use as fuel for power purposes. Under extreme conditions, all kinds of crudes have been used for fuel, but they are better suited for the purpose when the gasoline and burning oil have been removed. Fortunately it pays to take out these portions, and therefore the so-called "skimming" plants have been successful. As a rule wherever these fuel oils have been used an advantage has been demonstrated. This includes all kinds of power plants, locomotives, and finally the marine engine. The advantage on locomotives is evident, for the size of a locomotive is limited by the amount of coal that a fireman can feed in a given time. Thus in the Northern Rocky Mountains the limit of size has been reached by this human limitation, at least until an oil supply can replace the coal. Then the size and efficiency may increase again.

Internal Combustion Engines.—For marine power, oil's efficiency includes, besides increased capacity, elimination of the smoke nuisance on passenger craft, with its attendant cost of paint, and of the smoke danger for war vessels.

Oil in the Navy.—The effect of this is that more than 25,000,000 barrels of oil per year must be set aside for naval purposes in the United States, and the merchant marine will require as much more. Further it must be remembered that the great majority of the known petroleum resources of the world are here in the United States. One effect of this was seen in the days of the flood of oil at Beaumont, Texas, with oil selling as low as 10 cents per barrel, where it was recklessly applied to any purpose. Every effort was made by those interested in the welfare of oil to induce the changing of the use of petroleum into other more conservative uses, such as distilling out as much gasoline and kerosene as the oil will yield, and converting as much as possible of the residuum into various lubricating oils and thus avoiding the use of oil as a low grade fuel in competition with coal. Now, however, for the reasons given, the use of oil in internal combustion engines has become one of its most beneficial uses.

In the future, therefore, we can expect the very best utilization of our valuable oil supplies to proceed along the lines of burning it for the production of power. This method of burning oil constitutes an example of modern conservation of resources.

Oil for Good Roads.—Another use that can really be considered as consistent with the conservation of our mineral supplies is the use of petroleum residues for making good roads. Road oil, as manufactured from Texas and mid-continent oil residues, probably produces as great economy in national life as any other use to which it can be put.



Lubricating Oils.—Meantime we must not lose sight of the fact that modern progress would cease, the movement of all machinery would stop, were it not for mineral lubricating oils. The former supplies of animal and vegetable oils suitable for lubrication are trivial compared with the demands of modern machinery. Mineral lubricating oils are as essential to machinery as the telephone is to the conduct of business affairs.

Protection of Future Supply.—As already pointed out, we are producing more petroleum than we need, and we are obliged to export the surplus. This surplus goes to the ends of the earth, and from the broad standpoint of the world's economy it is necessary for progress. From the more limited standpoint of the economy of the United States, it would be better to keep it at home until needed.

The necessity for thus husbanding our petroleum resources is so evident that it will be accomplished, partly by the purchase of large tracts of petroleum lands by large corporations who will hold these supplies for the future, and partly by the withdrawal by the National Government of such oil lands as remain on the national domain in the interest of future use. A most favorable sign of the times is the agreement between companies in California that each shall keep back a certain number of hundred feet from the dividing line in order that neither party will draw the oil from the other's territory—an arrangement which makes it no longer an inducement to withdraw the oil from one tract to prevent its being exhausted by the wells of a rival tract. The extension of this policy is consistent with common sense and business interests. Two recent very successful feats in oil engineering have greatly improved the prospects of a long continued natural gas supply in the United States. A great source of loss in this country has been the waste of at least 100,000,000 cubic feet of natural gas per day in the Caddo field in northwestern Louisiana. Repeated claims have been made that these oil and gas wells could not possibly be controlled. Within the last two months the engineer of the Caddo Gas and Oil Company, of Shreveport, Louisiana, has completely controlled one of these great volcanoes of gas, water and oil, and the feat was so easily accomplished as to make it altogether probable that the other wells will be quickly controlled in the same way.

At the time this article is being written, another great problem is being solved in this same Caddo field. An oil well gushing at least 20,000 barrels per day, together with a large quantity of natural gas, has been on fire for several weeks, defying all attempts at extinguishing the fire or controlling the flow. As a last resort a tunnel has just been finished. The intention is to cut the pipe and divert the stream of oil through the tunnel and thus extinguish the fire and control the well.

With the steps thus in progress for the conservation of oil resources, it is probable that the oil supply of the United States is in a fair way to be protected for many generations to come, and it is certain that the methods of using this material are more satisfactory than for most other minerals.

OIL IN EUROPE

Injury to Lumber by Fungi

BLUE and black stains on lumber stored in yards decrease the value of the lumber, without, however, injuring the wood, since it has been found that the fungi which cause the stains feed upon the materials within the cells of the sap wood, and do not destroy the fibers. These fungi are largely of the black knot family, and the most common are species of *Graphium* and *Ceratostomella*. It has been the custom of the lumber companies to dip the wood in solutions of sodium carbonate or bicarbonate immediately after the sawing, but the results have been very uneven. To find out why the alkaline solutions sometimes prevented the development of the fungi, and at other times had no effect whatever, Miss Caroline Rumbold started a series of experimental cultures at the Missouri Botanical Garden in St. Louis.

Nutrient media were prepared containing from one-half to two per cent sodium carbonate, and others with similar amounts of citric acid. The spores of *Ceratostomella* germinated and the fungus thrived on the acid media, and on those containing 0.5 per cent of Na_2CO_3 but not on those with 1 per cent or more of the alkali. Freshly cut sap boards of yellow pine and red gum were then dipped in hot and in cold solutions of sodium carbonate and of sodium bicarbonate, of various strengths from 1 per cent to 10 per cent. These boards were inoculated with the spores of the fungus and kept in chambers with a saturated atmosphere. Controls were simply dipped in water, and some of the red gum boards also in sulphuric acid (5 per cent and 10 per cent). The fungus developed on all the controls, including the sulphuric acid boards, and on most of the boards dipped in the alkaline solutions. The hot dip was found to be more effective in inhibiting the growth than the cold solution, and the carbonate of 7 to 8 per cent as effective as bicarbonate solution of 8 to 10 per cent.

Increase of Crop Yield in Germany

ON the twenty-fifth anniversary of the German Agricultural Society there was published a table showing the progress in the yield of various farm crops during the quarter century. Some of the items are given below, the figures representing pounds per acre.*

	1885	1910
Rye	1,050	1,486
Wheat	1,344	1,771
Barley	1,315	1,745
Potatoes	8,989	12,470
Oats	1,255	1,719
Hay	2,910	3,863

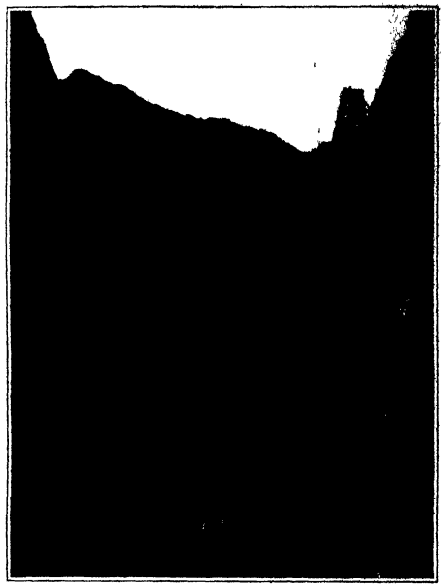
It is pointed out that this progress is not due merely to better treatment of the soil or to more abundant fertilization, or a more intelligent selection of seed, etc., as is commonly supposed, but also in a measure to a differentiation of crops in accordance with the adaptability of each particular type of soil.

*Original report, quintals per hektare.

Reclamation and Home-making

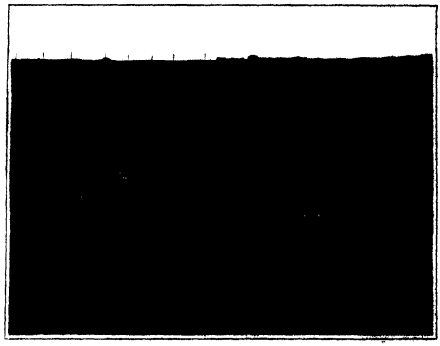
I.—Review of General Conditions in the Reclamation Service

By F. H. Newell, C E., Director



ONE of the most far reaching but little known works of the United S[illegible] is that of the reclamation by irrigation of arid lands. These lands form about one third of the total area of the United States and although only a small proportion can be irrigated yet the farms and homes which may be created have such great value as to become a notable addition to the wealth of the nation

It is not however the object merely to reclaim these lands and to add them to the productive capacity of the nation Far beyond this is the higher object to be attained that of rendering these areas capable of furnishing homes for thousands of citizens The lands are not irrigated that they may add to the wealth of a few but when reclaimed they are subdivided in tracts each sufficient for the support of a family and are disposed of to persons who will live upon the land for five years cultivate it and become self-supporting citizens and taxpayers



The public lands thus reclaimed are not sold but are given away to actual homesteaders The cost of the reclamation however must be returned in ten annual instalments Thus for example if it has cost $30 an acre to bring the water to a given tract and it is found that 40 acres is adequate for the support of a family an individual is allowed to file upon this 40-acre tract title is obtained after five years residence and cultivation and payment to the government of the cost of reclamation which in this case is $1 200 in annual payments of $120 each He obtains an opportunity of acquiring a home and a piece of land which rapidly increases in value because of the fact that as other people flock in and take up the adjacent lands a relatively dense population is established towns grow up and there is an increment of value beyond the result of his own efforts—for these lands ultimately are worth $100 or more per acre

There has already been invested about $60 000 000 in this work and this investment is being increased at the rate of approximately $1 000 000 a month This money is not being paid directly by the tax payers as it is not derived from domestic or foreign imports but from the disposal of public lands The moneys thus obtained are credited to a fund in the treasury placed at the disposal of the Secretary of the Interior and expended through what is known as the Reclamation Service an organization composed of engineers with necessary technical and clerical assistants

The law authorizing this work known as the Newlands Act from Senator Francis G Newlands of Nevada was passed on June 17th 1902 It is very general in character calling for certain results and laying down a few broad lines to be followed All of the intricate detail had to be worked out It was as though a great business enterprise had been authorized without indicating dimensions character of structure or any facts excepting that certain funds of unknown amounts were to be expended to accomplish results in localities widely separated The location of the works for the most part in regions remote and without adequate transportation facilities the magnitude and complex character of the engineering features and the difficulties encountered in adjusting the diverse interests of private owners furnished innumerable problems the solution of which required a vast amount of investigation and study The first thing after the passage of the act was to get the engineers The natural thing to do was to continue in the work the men who had been studying the subject for many years, and then to select a few localities and begin the work

SHOSHONE PROJECT, WYOMING

There were demands from all parts of the arid West that work should be undertaken at once, and the people were inclined to chafe at any delay in the beginning of actual construction It was difficult to make them understand the need of preliminary study and investigation they wanted to see the dirt flying and the big dams rising in the canyons.

It was known as the result of previous investigations that several projects undoubtedly were feasible, and that certain large structures must be built in connection therewith Work was, therefore, begun on some of these before all the plans could be elaborated Those matters upon which there could be little question were at once entered upon, the connected details and plans for additional structures being worked out while building progressed.

The result is that a large amount of work has been accomplished in a short time and a reputation established for prompt execution as against the idea that government officials could not move expeditiously

At the same time, every effort has been made to preserve accurate records of the cost of the work and to study all of the economies which were practicable under existing laws and regulations Cash discounts were sought, as well as wholesale rates Transportation of material was secured at the lowest obtainable terms and the operations put upon a business basis What this means can never be appreciated by a man who has not worked for the government, and who has not run against the innumerable complications growing out of a century of corrective legislation and executive requirements Transacting government business on business principles is like trying to drive directly across a settled valley which is fenced in every direction by barbed wire The old inhabitant knows the highways and byways the gates and the openings and can go across the country with considerable speed but the newcomer who does not know these is constantly getting entangled in wire fences and in controversy with the people and is forced to back out and finally go by the most roundabout road.

The Reclamation Service has been particularly fortunate in its ability to traverse rapidly and effectively the entanglements of legal obstacles discovering the openings and short cuts which expedite work

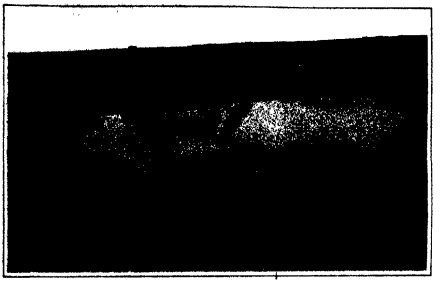
Acting under a very general law in which results only are called for, it has been possible to avoid many of the embarrassments of the more elaborate enactments of Congress, where the attempt has been made to describe in advance all sorts of remedies for every kind of emergency. Nevertheless, there are enough general laws and restrictions to necessitate the greatest skill and care in making expenditures without getting one's self into continual trouble.

One of the methods adopted by the Reclamation Service for avoiding delay and [illegible] to have the [illegible] of funds placed in the hands of a considerable number of local agents. These men are of the employees who have been [illegible]

disbursing officers in large enough so that if the accounts of one are suspended on technicalities, another man can take charge, while the first devotes his time to satisfying requirements of the Treasury officials, thus avoiding delays.

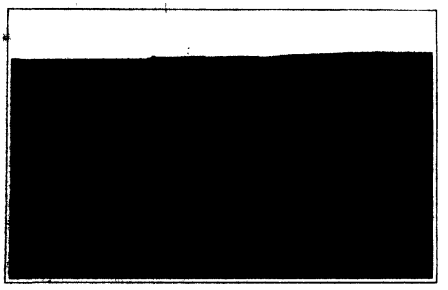
The business methods have been the subject of continued study and examination by experts and have been so perfected as to serve as a model for various contracting or other corporations, which have practically adopted the general scheme of cost-keeping, modifying the details to suit private conditions.

It is recognized, of course, that the government bureau cannot work as economically in some ways as a private corporation, because it is loaded with requirements of advertising for competition in all purchases, of elaborate preparation of all papers having to do with disbursements, with the attaching of numerous signatures, growing out of various laws, with almost innumerable restrictions imposed from time to time to meet special conditions and also others which were never anticipated when the regulations were drawn. Nevertheless, experience has shown that it is possible to prosecute business with reasonable economy and speed. As proof of this it may be stated that already nearly a million acres of lands have been furnished with water, and about 14,000 families are on these lands These beneficiaries of the law are beginning to pay back into the Treasury their *pro rata* share of the cost of the work.



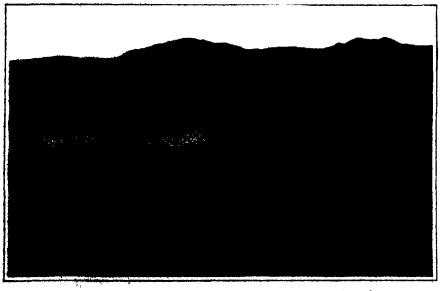
The results attained are an example of what may be accomplished in the practical carrying out of the conservation ideas, so ably presented by Theodore Roosevelt and Gifford Pinchot. In fact, the reclamation work may be considered as part of the great programme of national conservation, being joined with the protection and use of the forests, the saving of the water powers, and other natural resources and monopolies for the people. The outcome shows that it is possible for the National Government, through skill and competent officers, to grasp these great opportunities and to develop for the common good the resources, which, up to the present time, have been turned over to the great corporations, on the ground that it is impossible for the people to help themselves through a popular form of government

In carrying out the objects of the Reclamation Act, and embodying the ideas therein contained in feasible structures, there have already been built reservoirs for conserving the waste waters and having a capacity such as would cover four and one-half million acres with water one foot in depth. To distribute this water to the land, or take it from various streams, there have been constructed nearly 350 miles of canals of large size, that is to say, carrying over 800 cubic feet per second, while in smaller canals or distributaries, there are several thousand miles. The tunnels by which the water is carried under mountain masses or through obstacles aggregate in number nearly 70, with a total length of 100,000 feet There are literally thousands of smaller structures, such as gates, turnouts, flumes, and bridges, each of which has required more or less engineering skill and forethought The material excavated in building the canal system has aggregated 60 million cubic yards of earth, and nearly 5,000,000 yards each of loose rock and of solid rock In building the dams and other structures, there have been used over a million barrels of cement



These figures will give some idea of the gross magnitude of the work; but to the men interested in scientific or engineering facts, they are less instructive than a few details concerning some of the more interesting or typical of the works now built

The results accomplished, however, are far more important than those which can be shown in figures of quantity, size, or cost They relate to those higher and larger objects of life which rank above mere material prosperity, in that they contribute to the development of a citizenship, of far greater importance to the nation than the possession of wealth The object of the Reclamation Act, while directed immediately toward the construction and maintenance of irrigation works is really more far reaching, for these works are the foundation for homes for its citizens and their use is conditional upon the ownership of the reclaimed lands in small tracts sufficient for the support of a family This means that there can be no land monopoly Each farmer or beneficiary of this law can obtain land or water sufficient only for his own use He must be one of a group of independent landowners living in relatively thickly settled communities, where success is attained through intensive cultivation, and where there thus results the ability to enjoy the comforts or even luxuries which are incident to a carefully cultivated, densely populated, or suburban locality The man who has been a mechanic or has pursued some trade in the city or has wandered about the face of the earth is offered an opportunity to secure for himself a home, with reasonable expectation of competence in his old age He must endure at first the privations of pioneering and must have energy and use good judgment, but there is no occupation in which a more substantial reward will come for efforts intelligently expended



From the standpoint of the common wealth, the gain is great in transforming the indifferent citizen, who has been living in an apartment or wandering about from place to place, into a settled, taxpaying voter, interested in everything which concerns the locality, the county, the State, and the nation.

II.—The Engineering Work of the Reclamation Service

By A. P. Davis, C. E., Chief Engineer

In the early days of the operation of the Reclamation Act the principal engineering problem was the examination of irrigation projects and the selection for construction of the more feasible of these, modified by the legal requirements of geographic distribution.

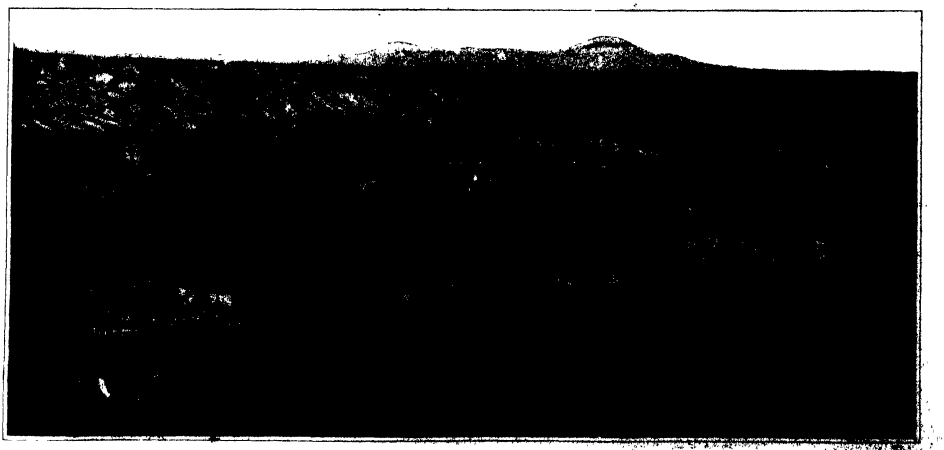
The local engineers of the service made preliminary surveys which were inspected from time to time by the consulting engineers, until what was deemed the most feasible project presented by local conditions was whipped into shape and submitted to a board of experienced engineers for the purpose of determining its feasibility. A report of this board was submitted to the Secretary of the Interior, and one by one projects were approved in all of the States to which the act referred, excepting Oklahoma, in which no feasible project has yet been found. Construction began in the Carson Valley, Nevada in September, 1903, and soon after in various other States, until the approved projects were all under consideration. The construction work accomplished since the passage of the act, up to December 31st, 1910, is given in the table on page 148.

The diversion of water for irrigation in the arid regions of the United States is not new, but has been in progress for over half a century. Through the efforts of individual and corporate enterprise, the smaller and easier projects have been mostly carried out—these usually involving the diversion of the natural flow of a small stream over a smooth valley adjacent. As the smaller and cheaper projects are developed and those involving heavier work are undertaken, the development becomes more and more difficult for private capital and less certain of profitable returns. At the time of the passage of the Reclamation Act these causes had greatly checked the development of irrigation enterprises by private investment, and the engineers of the service found the projects usually involved engineering construction of considerable magnitude and difficulty. More than three-fourths of the projects undertaken require the construction of an expensive storage reservoir, and the majority also required the construction of expensive diversion dams, tunnels, aqueducts or other structures relatively difficult and expensive, and often requiring a long time in completion. For example, the Roosevelt dam in southern Arizona, recently completed, contains over 350,000 cubic yards of masonry, and forms the largest artificial reservoir now in existence, the construction of this reservoir required the expenditure of nearly $300,000 in wagon roads alone, to make the region accessible and to replace public roads submerged by the artificial lake. The heavy cost for transportation also compelled the manufacture in the vicinity of the cement, lumber, brick and sand necessary in this large construction.

Map showing the various projects of the Reclamation Service.

The storage dam on Shoshone River in Wyoming is the highest dam in the world, and the Reclamation Service is now beginning the construction of a still higher dam in Idaho.

The Gunnison Tunnel in Colorado, recently completed, is nearly six miles in length and was constructed under extreme difficulties presented by the presence of hot water and gas in great quantities, and the shattered condition of the formations pierced. The contractor for this tunnel failed and the work was carried out by the direct employment of labor under the engineers of the service; it required nearly five years in construction, and an expensive storage reservoir must yet be built to permit the complete development of the lands under the project.



Some projects require for their proper development a very broad and comprehensive study of conditions over a large water-shed, usually extending across State lines.

A typical example of this kind is the North Platte Basin, where a storage reservoir has been completed which will store over one million acre-feet of water, and will control the entire flood of the North Platte Basin in years of ordinary flow. This reservoir will hold the water that would run to waste in the winter months, and also store the excessive flood waves from melting snow in the months of May and June for use during the late summer and autumn, when the natural flow of the river is at its minimum.

The construction of this reservoir to about the capacity above mentioned is indispensable to the complete development of the water supply of the North Platte River, its capacity is far above the needs of the government project now constructed at a cost of about $3,000,000. The surplus storage may be used in the development of additional projects in the basin, and in completing the water supply for similar private irrigation enterprises previously instituted.

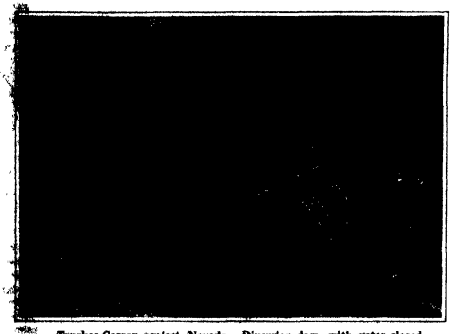
The far-seeing policy which prompts the construction of this large reservoir under these circumstances would hardly be feasible for private enterprise, which must assure itself of an early return of the invested funds; yet, such policy as that followed was absolutely essential for the proper conservation of the natural resources. The same principle holds true with the majority of the larger projects undertaken.

An interesting fact, incidental to some projects,

Pathfinder dam, Wyoming; 22-horse freighter hauling cement 45 miles to dam site.

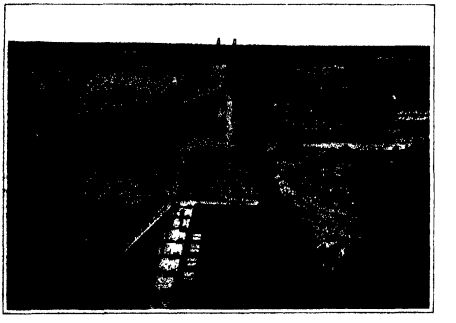
NORTH PLATTE PROJECT, NEBRASKA-WYOMING

...ation of the water power made available ... irrigation works for the increase of the water ... pumping from underground sources, and ... utilizing the existing supply by rais... of it to higher levels which cannot be ... gravity ditches.



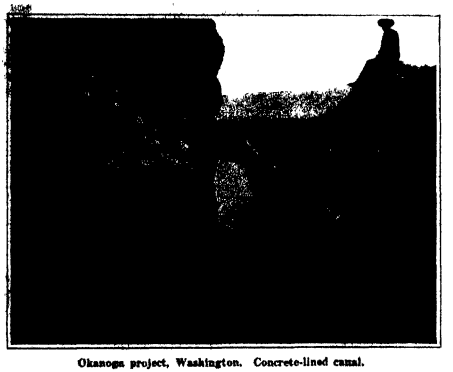
On the Huntley project in Montana, the main canal ... point where topographic conditions require ... dropped to a lower level to avoid a long ... of broken country; the power generated by ... water at this drop is utilized for pumping ... of the water to an elevation considerably ... than the main canal, which it would not have ... possible to cover by gravity. This is accom... by the device of "dry pumping" in which the ... water is received in an inclosed casing con... a large machine which consists of a turbine ... wheel and a centrifugal pump combined as one machine, on one shaft, in one casing, and the water received is divided into two parts, one of which emerges from the turbine wheel at the lower level and is thus used for irrigation, while the other portion is raised to a high level—much higher than the main canal—and used there for irrigation.

On the Yakima project in Washington a similar result is obtained by a battery of 11 large hydraulic rams.



On the Salt River project the power developed at the storage dam is converted into high voltage electric current, and transmitted to the valley, where the fertile land greatly exceeds the water supply and the latter is increased by pumping from a large number of wells distributed throughout the region where ground water is known to exist. In this way about 40,000 acres of land which could not otherwise be irrigated, is added to the area of the cultivated land.

A portion of this pumped supply is utilized in relieving the needs of the Indians on the Pima Reservation, whose industry and wealth, and whose urgent needs, have been so much discussed in the public prints.



On the Minidoka project in Idaho a diversion dam about 50 feet in height has been built to divert the water upon the neighboring valleys, and about 80,000 acres of good land is thus irrigated by gravity. It is necessary to allow a large quantity of water to flow past the dam during the irrigating season, for the satisfaction of irrigation appropriations at points further down the stream. This water is taken from the dam under a head of about 46 feet, and by means of hydro-electric machinery is converted into electric current and transmitted about 15 miles to the southwestward, where it is used for pumping water from the main canal to irrigate about 50,000 acres of land too high to be reached by gravity. This is some of

the driest land in the West, and for about [illegible] if the water is lifted over 90 feet by [illegible]. The power used for this purpose is generated, of course, only in the irrigating season, from April 1st to October, inclusive, and during the winter months would be available for other uses, if any such [illegible] instead; but as the community is young and [illegible] developed, there is little demand for power [illegible] when it is available only during half of the [illegible]. It happens, however, that this region is rather [illegible] from coal supply, and efforts are being made [illegible] ize the surplus winter current for heating the residences and business houses in the villages which are growing up on the project. This region promises to develop into one of the few where it is commercially feasible to use electric energy for heating.

One of the cardinal principles of irrigation is that it must be accompanied by an early system of drainage, otherwise the application of water by irrigation is likely to produce injurious effects by the waterlogging of a portion of the land, and the consequent rise of injurious alkali from great depths to the surface, where it becomes harmful to vegetation. Often it is necessary to provide artificial outlets for the drainage ditches with which each farm must be provided; and it is, moreover, impracticable to plan these to the best advantage before the exact nature of the problem has been indicated by the effects of a few years of irrigation. The varying underground conditions in the matter of porosity are shown by the actual results of irrigation, and it then becomes feasible to provide a drainage in time to prevent serious injury.

III.—Summary of the Reclamation Projects

THE following is a brief recapitulation of four signed articles written by the supervising engineers of the various projects. Unfortunately, the original articles are too lengthy for inclusion in the present issue. They are published in the current issue of the SCIENTIFIC AMERICAN SUPPLEMENT, *together with a large number of illustrations from photographs furnished by the Reclamation Service.*—ED

Washington Division. Charles H. Swigart Supervising Engineer.

The Washington Division comprises all of the State of Washington and the extreme northern part of Idaho. The Reclamation Service has completed one project, the Okanogan, and is now constructing the Yakima project. OKANOGAN PROJECT.—The Okanogan Project, now completed, provides for the irrigation of land in the valley of the Okanogan River. Water is stored in Salmon Lake, and in Conculli Reservoir, the two having a combined capacity of 15,000-acre feet. An earth dam a thousand feet long, 64 feet high, has been built across Salmon Creek. This is the only dam constructed by the hydraulic hill method by the Reclamation Service. The irrigable land, amounting to about 8,650 acres, is of volcanic ash, sand and gravel. The building charge per acre is $65, and the annual maintenance and operation charge is $2. YAKIMA PROJECT.—The Yakima Project embraces all the land in the Yakima Valley that can be watered from the Reclamation Service works, together with some lands in the Columbia Valley, near the mouth of the Yakima River. This project, for convenience, is divided into the Storage Kittitas, Tieton, Sunnyside and Wapato Units, with the High Line, including the Benton Unit, or the Benton Unit alone, as alternative propositions. The Storage Unit includes works for impounding the flood waters of the Yakima and its tributaries, in five separate reservoirs, which will have a total capacity when fully developed of approximately 928,000 acre-feet. The Kittitas Unit, for which surveys have been made, embraces 62,000 acres of land on both sides of the Yakima River. The Tieton Unit, containing some 34,500 acres, lies west of the city of North Yakima, and between the Naches River and Ahtanum Creek. The Sunnyside Unit, containing 100,000 acres, receives its water from the Yakima River, just below Union Gap. The Wapato Unit consists of 114,000 acres on the right bank of the Yakima River, just below Union Gap. This land was allotted to the members of the Yakima tribe of Indians. The Benton Unit includes from 120,000 to 150,000 acres of land on both sides of the Yakima River, near its junction with the Columbia. The High Line Canal will, if constructed, furnish water for the lands on the left bank of the Yakima River above existing canals.

Northern Division. H. M. Savage Supervising Engineer.

The Northern Division comprises the States of Montana and North Dakota, and South Dakota, and northern Wyoming, and includes the Missouri River drainage basin, with the Yellowstone River in Montana and the Big Horn River in Wyoming. Within this area the construction of seven Reclamation Service irrigation projects has been authorized. Construction has progressed to the extent that at least one unit of each project has been completed, and all the large feature structures on several of the projects are now constructed.

The flat grade of the Missouri River rendering the construction of gravity irrigation canals impossible, the construction of the NORTH DAKOTA PUMPING PROJECTS was found to be dependent upon the development of power from the ample fuel supply in local lignite beds, and its transmission electrically to operate centrifugal pumps mounted on floating barges on the Missouri River. The barges are taken out of the stream at the end of the season and again launched at the beginning of the next irrigation season. THE LOWER YELLOWSTONE PROJECT.—The Lower Yellowstone Project in eastern Montana and North Dakota covers 60,000 acres, and is nearly completed. It includes a timber crib rock-filled diversion dam, which provides an overflow depth of 25 feet. The Yellowstone River at the site of this dam has a maximum flood flow of 160,000 cubic feet per second. THE SHOSHONE PROJECT in northern Wyoming will reclaim 164,000 acres of land, with a feasible extension to cover 300,000 acres. The principal features are the Shoshone Dam, the highest masonry dam in the world (328.4 feet), which regulates the discharge of the two Shoshone rivers, and whose reservoir is now filled to the spillway, and the Corbett Tunnel, three and a half miles long, with a discharge capacity of 100,000 cubic feet per second. THE HUNTLEY PROJECT on the Yellowstone River has an area of 32,000 acres, of which 28,000 acres is now settled. The success of the Huntley settlers is unprecedented. The crops on the irrigated area the second season realized a value of $25 per acre. The project has now thirteen public schools and six church organizations. THE SUN RIVER PROJECT, west of Great Falls, is the largest in the division, the available water supply being from 200,000 to 300,000 acres. It is now entering on its third season of operation. The main features are high storage dams and a canal of 2,500 cubic feet per second capacity. THE MILK RIVER PROJECT in northern Montana depends on the waters of the St. Mary drainage basin, which discharges into Hudson Bay. It involves 100,000 acres of land, and four million dollars has recently been provided for carrying on the work. INDIAN RESERVATION IRRIGATION PROJECTS.—The Reclamation Service is constructing works on the Flathead, Black Feet and Fort Peck Indian reservations, each of which has an area of about 150,000 acres of irrigable land. Most of this has been allotted to the Indians in severalty, and the receipts from the sale of excess lands will return the cost of the irrigation works. The ultimate development of the FLATHEAD PROJECT involves the construction of fifteen storage reservoirs, and the construction and operation of a hydro-electric pumping plant.

Idaho District. J. T. Whitworth Supervising Engineer.

The Idaho District embraces that portion of the Snake River Basin from its headwaters in the Yellowstone National Park in Wyoming to its confluence with and including the Salmon River, a total area of about 90,000 square miles. It embraces the Boise, Minidoka and Snake River Storage projects. BOISE PROJECT.—This embraces 243,000 acres of land on the south side of the Boise River between its confluence with the Snake River and the city of Boise. The principal engineering features are: First, a storage dam, 1,025 feet on the crest and 340 feet high, which will be the loftiest dam in the world. It will impound 207,000 acre-feet of water for use in the low water period, on lands in the upper portion of the project. The lower portion will be supplied from the Deer Flat Reservoir, which is filled by water diverted from the Boise River, and will have a capacity of 170,000 acre-feet. The main south-side canal for carrying the water has a capacity of 3,500 feet per second, and is forty miles in length, six of which are lined with concrete. MINIDOKA PROJECT.—The principal engineering feature of this project, which embraces an area of about 132,000 acres on both sides of the Snake River in central southern Idaho, are the Minidoka Dam, headworks, power plant, and pumping stations. The dam, 736 feet long and 86 feet high, is of the rock-filled type. It is flanked by the power plants and north side headworks on the north and a solid concrete spillway 2,400 feet long, and the south side headworks on the south side. The power plant includes five turbo-generators of 1,500-kilowatt capacity, which, during the irrigation season, pump water to 47,000 acres of high land, and also serve to furnish the towns on the project with light, power and heat. Nearly all of the business houses and many of the private houses in the thriving towns of Rupert, Heyburn and Burley use electrical energy for heat. The three pumping stations on the south side lift the water in three stages to a total height of 90 feet. By means of reinforced concrete piers, the water of the reservoir can be raised five feet, thus increasing the storage capacity and the available head on the turbines. SNAKE RIVER STORAGE.—This contemplates the storage of flood water of the rivers in reservoirs, so as to regulate its flow to conform to the needs of irrigation and power. Jackson Lake Reservoir, just south of the Yellowstone National Park, is completed. A reinforced concrete dam and an earth dike form a reservoir of 850,000 acre-feet capacity.

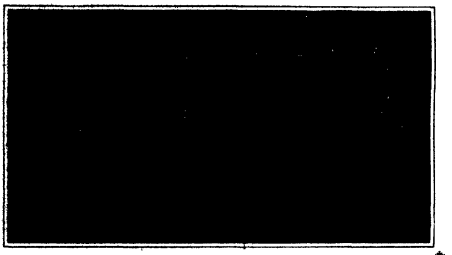
Intermountain District. R. F. Walter Supervising Engineer.

The work of the Intermountain, sometimes known as the Central District of the Reclamation Service, covers a territory in which irrigation has been employed as a means of distributing moisture to grow crops since the earliest settlement of the Mormons, who turned their attention from the rocky, arid soil to the work of directing the waters from the streams onto the barren land. They were so prepossessed that agriculture without irrigation was impossible that they [illegible] try [illegible] and engineers the value of [illegible] waters in reservoirs, for use after the [illegible] had been reduced to flow. This work began about [illegible] since which time thousands of [illegible] acres have [illegible] cultivation [illegible]

The Conservation of Fishery Resources

How Legislation May Prevent Ruthless Waste

By Dr. Hugh M. Smith, U. S. Deputy Commissioner of Fisheries



NEARLY forty years before conservation had become a household word in America, one branch of the federal government had entered on a course of action having for its direct object the maintenance of the supply of useful water creatures. That work has continued uninterruptedly and with constant augmentation to the present time, and in it the Federal Government as represented by the Bureau of Fisheries has co-operated for many years with the fishery departments of various States. Among all of our natural resources there are none that have been more flagrantly abused, none that are more in need of intelligent attention at the hands of conservators, and none that will respond more readily to decent treatment than the fishes and other inhabitants of our coastal and interior waters

Success of Fish Culture and Acclimatization.

The acclimatization of fishes in all parts of the country has been a potent supplement of fish culture proper and a valuable factor in conservation by reinforcing the strain on native fishes and by making exhausted waters again yield their quota of human food Among the noteworthy results of the introduction of fishes into a new environment are the cases of the shad and striped bass These excellent food fishes are not native to the Pacific Coast but were planted there by the government more than a quarter of a century ago. The slender colonies took root, thrived, multiplied, and spread to such an extent that both of these species are now reckoned among the commonest food fishes of the western seaboard, the shad having a coastwise range of four thousand miles and the striped bass being more abundant in California than in any Eastern State The entire cost of the introduction of these fishes into the Pacific States did not exceed $5,000. The market value of the catch to the fisherman to the end of the year 1910 exceeded $1,750,000. With the present trend of the shad and striped bass fisheries on the Atlantic Coast, it is not beyond the range of probability that the re-establishment of these fishes in eastern streams may depend on fry brought from the West.

Legislation and Regulation.

A co-ordinate if not a coequal factor in fishery conservation is legislation. For the protection of fish in interstate waters, well considered restrictive legislation, supported by local sentiment, may accomplish much; for interstate and boundary waters, or for fishes that migrate from one jurisdiction to another, legislation has often, perhaps usually, failed The failures have been serious in some regions and in the case of some species, and afford the strongest possible argument for federal control and also regulation

Catching and sorting the brood fish at a government trout-cultural station in the Rocky Mountains.

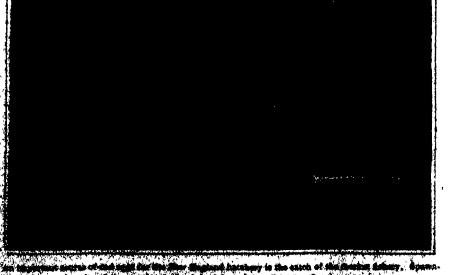
Various species of trout are hatched in large numbers, and numerous lakes and streams are kept bountifully stocked

Stripping and fertilizing trout eggs at a station in the Rocky Mountains.

An event which gave promise of resulting in one of the great conservation measures of this generation was the assumption by the federal government of jurisdiction over the fisheries of the waters contiguous to the United States and Canada from Passamaquoddy Bay to Fuca Strait, followed by the conclusion of a treaty between the United States and Great Britain under which joint fishery regulations were to be drawn up, ratified, and enforced by the two countries This assumption by our government of jurisdiction that had formerly been exercised by the States was undertaken reluctantly and only after protracted evidence of the inability of the States to enact and enforce legislation that was harmonious and adequate It is therefore very unfortunate for the welfare of these extensive fisheries that the recommendations of the special commission appointed under the treaty have not been put into effect

Whitefish of the Great Lakes.

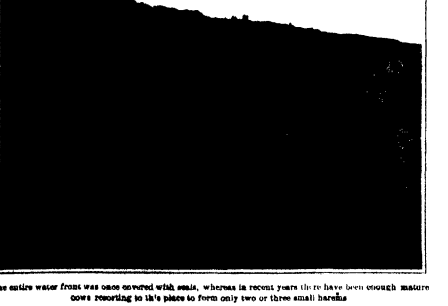
The case of the whitefish of the Great Lakes is serious and radical action is necessary to arrest a decline that has been in progress for many years The regulations and restorative measures provided for the treaty would undoubtedly prove a boon to the whitefish fishery and would soon convert a dwindling industry into a flourishing one



The fact that the supply of whitefish has not been maintained even at the reduced point reached in 1880 or 1890 has resulted in the direct loss of many million dollars to the fishermen and the indirect loss of many hundred thousand dollars to Federal and State Governments because of their abortive efforts to restore by artificial propagation and the enforcement of restrictive legislation There is no fish that has been hatched artificially in larger numbers than the whitefish, while enough legislation has been addressed to it to sink a battleship The catch has declined eighty per cent in twenty years, showing how powerful are the anti-conservation forces in operation

There is absolutely not a single valid reason why the abundance of this great food fish should not have remained practically unimpaired for untold generations and at the same time vast quantities have been caught for market. The average number of eggs laid by a whitefish is 25,000 All that nature required, all that the unimpaired perpetuation of the fishery demanded, and the least that common sense could have granted was that a single pair of fish from the 25,000 eggs should have been permitted to reach maturity and spawn

Oysters and Sponges.



After a precarious existence of many years, the oyster has gradually come under the influence of cultivation, and along much the greater part of our extended coast its conservation is an assured fact and need never occasion any further concern The finan

(Continued on page 154)

An illustration of the kind that the fish-displayed hatchery is the catch of the Alaskan fishery. Spawn-taken from the female, fertilized therein, and now the eggs of which are hatched.

Stripping and fertilizing trout eggs at a fishing station.

The entire water front was once covered with seals, whereas in recent years there have been enough mature cows resorting to this place to form only two or three small harems

A depleted fur-seal rookery.

The Use and Waste of Our Coal Supply

(Continued from page 138.)

These problems are intricate, and their satisfactory solution doubtless remote, but they are of such importance as to be worthy of the best efforts of the Government and of its private institutions and individual citizens

In engineering and architecture we hide our ignorance as to the strength and other properties of structural materials behind the well-sounding phrase, "factors of safety" In these important and intricate fuel problems we hide our ignorance and rest our laurels concerning these losses under the equally comforting expression, "transformation of energy" What American industry needs is technical information, accurate fundamental data, such as comes from varied, extended, continuous, well directed, and scientific research

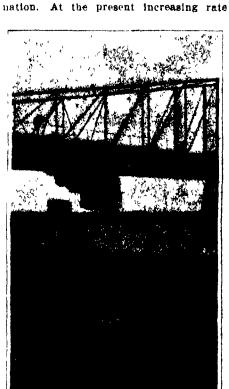
Each recent year has witnessed some advance in the line of greater fuel efficiency, and while each advance has been small, the aggregate has during the past decade raised the percentage of heat units converted into mechanical work from five or six to nine or ten, and slightly more in a few cases The gas producer and gas engine, the steam turbine, and the improved reciprocating engine, represent steps in this advance So does also the

Coal car is picked up bodily, turned over, and discharges to chute.

development and introduction of the several types of automatic stokers these latter contributing to efficiency and at the same time lessening the smoke nuisance from modern power plants

These automatic stokers and special grates have further contributed to the conservation of resources by making possible the more efficient burning of fine or slack coal which formerly was relegated to culm piles as waste and as such to be burned in the open air Briquetting is making another contribution along the same line Another step in the direction of practical conservation cleanliness and hygiene and one that should be pushed more rapidly is the location of the great power plants at the mines, and the burning there either in gas producers or specially constructed furnaces, of the low grades of coal now thrown away because they will not bear transportation, and the electric transmission of the power so developed to adjacent cities, towns and isolated plants

I look forward to a time and it cannot, I believe, be far distant when ample supplies of electricity so generated and brought into our factories and our homes will not only give us light and power, but will also cook our food and warm our houses



Two other marked advances in the economic utilization of coal deserve mention because of both their extent and their far reaching importance one is the large beginning in the manufacture of by product coke for the latest steel plants of the United States Steel Corporation, including the saving of such valuable by-products as creosote for the preservation of timber, and sulphate of ammonia, so largely used in the fertilising of crops. The other is the use in large gas engines of the blast furnace gases that formerly were entirely, and in many places are still largely wasted The losses in these two fields, added to the shameful waste of natural gases, still aggregate yearly from $50,000,000 to $100,000,000; but improvements are under way in all these lines

How These Mining Losses May Be Reduced.

No one questions the fact that these losses are real, nor are there any serious differences of opinion as to the proposition that these losses should be avoided Just how this best can be done is another matter, and one about which a difference of opinion may naturally arise The situation is full of interest, full of problems for the statesman the engineer and the economist, the consumer and the producer It involves the very essence, the purpose and the practicability of the movement for the conservation of resources

The case may be stated as follows:

We have but the one supply of coal, and this supply is essential to both the future and the present welfare of the nation. At the present increasing rate

Much coal is lost as dust during handling.

of use and waste of this supply, it will be used and destroyed while the nation is yet in its youth By mining and using this coal more efficiently, the life of the supply may be extended indefinitely, and both the present and future welfare of the nation thus properly safeguarded The coal operator does not practise wasteful methods by preference He is, however, operating under a system that encourages and even renders inevitable these wasteful practices, and for which system the public itself is largely responsible

A Federal statute makes it impossible for the coal producers to co-operate or combine with a view to fixing a common or non-competitive price for coal at the mine The demand for coal during the winter season of each year being much in excess of that during the warmer months, and the entire lack of storage facilities at the mines requires for this cold weather demand a mining capacity much in excess of that necessary for the summer needs Under such a system there is constantly in progress a fierce struggle for business, and a reduction to prices so low that they often fail to cover the actual cost of production—so low that safe and clean mining is discouraged and even rendered impossible Meanwhile, no two States have similar mining laws for the protection of life and property, nor will any State enact, or enforce, if it enacts, drastic legislative requirements, for if it does it thereby places its own mine operators at a serious business disadvantage in the sharp competition with operators in other States.

The remedy is easily stated, but not easily developed. The cut-throat competition should give place to a reasonable combination under such Federal or uniform State control of prices as would guarantee reasonable returns on mining investments, and require mining practices in which both accident and waste are reduced to an absolute minimum. This regulation and readjustment should be extended so as to include the freight and terminal agents' charges; and if this be properly done, safe and clean mining may be realized without material increase in the cost of coal to the ultimate consumer.

If to the American people the doctrine of conservation is a thing of substance and not a dream, if those of us who today are wastefully luxuriating in the abundance of inherited resources, have seriously at heart the rights and the welfare of those that are to come after us; if we are really in earnest about safeguarding the lives of the more than a million miners who labor underground for our comfort and welfare, we should enact and enforce the Federal and State legislation necessary for the accomplishment of these ends. We should render possible the business-like reorganization of this great basic industry. We should see to it that this underlying economic basis is sound, whether judged from the standpoint of the individual or the nation—from the standpoint of the present or future welfare of the nation.

The Vibrations of Metals

It has been contended that solid metals may reveal by their structure the vibrations to which they have been subjected. In explaining this phenomenon, experiments were made in England to show that a beautiful wave structure can be imparted to the surface of mercury by the vibrations of a tuning-fork, and that even the surface of solid lead which has been subjected to similar vibrations possesses a structure resembling that of a vibrating surface of mercury Mild steel was defined as a "solid solution" of iron and carbon, free from cinders Metallurgists have doubled the strength of steel as it was known in early days

Iodide of nitrogen a black powder, is one of the most dangerous of all explosives When dry the slightest touch will often cause it to explode with great violence

There appears to be a certain rate of vibration which this compound cannot resist In experiments to determine the cause of its extreme explosiveness, some damp iodide of nitrogen was rubbed on the strings of a bass viol It is known that the strings of such an instrument will vibrate when those of a similar instrument having an equal tension, are played upon.

In the present case, after the explosive had become thoroughly dry upon the strings, another bass viol was brought near and its strings were sounded At a certain note the iodide of nitrogen on the prepared instrument exploded

It was found that the explosion occurred only when a rate of vibration of 60 per second was communicated to the prepared strings Vibration of the G string caused an explosion, while that of the E string had no effect.

The question is often asked, What force least expected does the greatest damage to buildings? One architect's answer to this question may be a surprise to those who do not understand that it is the regularity of vibration that makes it powerful

"I venture to say," remarked this architect, "that you would never suspect that violin playing would injure the walls of a building Yet it certainly does. There have been instances when the walls of stone and brick structures have been seriously damaged by the vibrations of a violin. These cases are, of course, unusual, but the facts are established.

"The vibrations of a violin are really serious in their unsuspected, unbounded force, and when they come with regularity, they exercise an influence upon structures of brick, iron or stone. It follows, of course, that there must have been continuous playing for years to cause the loosening of masonry or to make iron brittle, but it will do so in time."

LEGAL NOTICES

PATENTS

If you have an invention which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best method of obtaining protection. Please send sketch or model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us in many cases to advise in regard to patentability without expense to the client. Our Hand Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN.

Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 12 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

HELP WANTED.

SUPERINTENDENT Metal Department of a large manufacturing concern, with whom frequently advantageous connections may be made, wants the making and finishing of articles from sheet metals. No one who is not thoroughly experienced need apply. Permanent position to right party. Address Metal Expert, Box 773, N. Y.

PATENTS FOR SALE

FOR SALE U. S. Patent No. 807,26 Automobile tool Consists of lifting jack, pick, shovel, hoe and pinch bar. Nothing of the type or character on the market. A sure seller Will sell outright for $4,000 Address S. S. Baird and William Peters, Jackson, Cal.

WANTED.

LOCAL REPRESENTATIVES WANTED Splendid income assured right man to act as our representative after learning our business thoroughly by mail. Former experience unnecessary We require is honesty, ability, ambition and willingness to learn a lucrative business. No soliciting or canvassing This is an exceptional opportunity for a man in your section to get into a big paying business with no capital and become independent for life. Write at once for full particulars. Address E. R. Marden, Pres. The National Co-Operative Real Estate Company, 1, 278, Marden Building, Washington D C

WANTED NOVELTIES FOR BUTCHERS Butchers' saw filing machines, etc For full particulars address J. Field & Sons, Barker's Road Kew, Melbourne, Victoria, Australia.

WANTED PARTNER. To defray expense for procuring patent on fire escape and selling rights same. Want partner to be taken in all countries except U. S. A., Canada and Great Britain. Control of it. Patent No. 802,775. Application filed July 26, 1905 Address Partner, Box 773, New York City.

MISCELLANEOUS.

FREE—INVESTING FOR PROFIT" Magazine. Sent six months' issue and I will tell you how to guarantee absolutely free. Before you invest a dollar anywhere—no matter how small or how large—write a card to any one who intends to invest $5 or more per month Tells you how to make $1,000 your own size to $25,000 —how to judge different classes of investments; the best legitimate Power of your money. This magazine six months free if you write to-day. H. L. Barber, Publisher, 426 W. Jackson Blvd., Chicago.

MAKE BIG MONEY operating a Dayton's Post Card Machine. Photo postal cards made and delivered on the spot in ten minutes. In the open air or in dark room. Successful. It does not require an experienced photographer to make the pictures. Pays 3 times gross profit of 500 per cent. Write today for free sample and catalogue. Dayton Specialty Co., Dept. V, St. Louis.

GINSENG Raising is the easiest way to make Big Money, or Little Change. One acre will yield $600 the second year. $1 will buy all you can raise. Grows anywhere. Requires your spare time only. If you are not satisfied with your present location, write me today. T. H. Watson, 116 Sherwood Ave., Louisville, Ky

ARTIFICIAL RAIN. New system of irrigation supplied with steam boiler. Will increase crops. Best and cheapest fertilizer to use money. Capital wanted to exploit same. Address Orange, W. Va., Box 773.

This New, Big, Self-starting Chalmers "Thirty-six"—$1800

THINK of a new, high powered Chalmers car with a Self-starter as regular equipment—for $1800! No more cranking, no more bother. Just push a button on the dash with your foot, and away goes your motor.

That isn't all. This car has a long stroke motor (4¼" x 5¼", developing 36 to 40 h. p.); four forward speed transmission; Bosch dual ignition; 36-inch by 4-inch tires; Continental Demountable rims; Mercedes type honeycomb radiator; dash adjustment for carburetor.

Furthermore this car has bigness, strength, proved durability, beauty, fine finish, comfort. Still further, it is a *Chalmers* car. On the radiator is the famous blue and white monogram.

And the price, including all these unusual features of value, is $1800.

A man at the circus for the first time viewed in amazement the giraffe. After looking the animal over for some time and inquiring if it had a name, he turned shruggingly away saying, "There ain't no such animal."

Many motorists, hearing of the Chalmers "Thirty-six" for the first time, then learning the price, have felt much the same way.

But they are wrong. There really is such a car as the Chalmers "Thirty-six," with the features named above—for $1800.

You can see this car now at our dealer's store near you. And it will look better to you there than it does in this advertisement. See it. Ride in it. Place your order as early as you can because there is sure to be an over-demand.

Ideal Car for the Farmer

This is an ideal car realized. A car perfectly adapted to the needs of the up-to-date farmer. The long stroke motor gives all the power and speed you can want, without useless burning of gasoline. The four forward speed transmission gives perfect flexibility for hills, sand, traffic and straightaway. Big tires, 36-inch by 4-inch, give riding ease and insure low tire upkeep bills.

The "Thirty-six" is heavy where weight means maximum strength, but there is no useless weight. We claim that this car is lighter than any other car of the same power, roominess and strength, and that it is stronger than any other car of the same weight.

This car overcomes the inconveniences of all preceding cars. The Chalmers Self-starter, air pressure type, does away with the trouble of cranking. Big tires and Continental Demountable rims rob punctures of their terrors.

Given Severe Tests

While the "Thirty-six" has every up-to-the-minute improvement, still there is not a single untried principle or part in its makeup. In November, 1910, we started three of these cars on the road to test them—one in the mountains of Pennsylvania, one in the sands and heat of Florida, and one in the varied conditions of the Middle West. They were run an average of 10,000 miles each before we O. K.'d the model for manufacture

Here is a big car—big radiator—big hood—big wheels and tires—big body with big roomy seats—big, strong frame—big axles—big all over, and yet it isn't a cumbersome, costly upkeep car

Not only has this car all of these unusual features of construction and convenience, but with them it has beauty. It is a *fine* car.

Compare With Many Cars

There are bigger cars than the "Thirty-six" and smaller ones. Cars of more power and of less. Heavier cars, lighter cars. There are higher priced cars and lower priced cars. And yet we ask you to consider this car on the basis that it is the most nearly ideal car for the farmer of all that are made.

Take the size, the power, the conveniences, the construction, the comfort, the beauty *and the price* into consideration in comparison with the same features on all other cars, and see if you do not conclude that in the Chalmers "Thirty-six" we have come most nearly to realizing the ideal car for the greatest number of people.

A Vote of Confidence

Public announcement of this car was first made on July 6th. Prior to that date, dealers had signed contracts for all we can make They were anxious to sign up for twice the number, but we had to allot just so many to each territory Since our announcement appeared, the Sales Department has received requests from more than two hundred other dealers, asking for the privilege of handling the Chalmers line in their section.

We asked dealers this year for exclusive representation for Chalmers cars in their price classes. Not one dealer was unwilling to grant this request, dozens of them giving up other lines in order to hold the Chalmers The vote of confidence which experienced dealers have given this new Chalmers car is one of the best possible guides for the individual buyer.

"30" Fully Equipped, $1500

The Chalmers "30" and Chalmers "Forty" are continued for 1912 and offer greater values than ever before because of the improved methods of manufacture and added equipment. The "30" sells for $1500, including magneto, gas lamps, Prest-O-Lite tank, Chalmers mohair top, and automatic windshield Last year this car so equipped brought $1750 The "Forty" sells for $2750, including the same complete equipment

More than a year ago, as the heading of an advertisement, we used an expression which was frequently heard in automobile trade circles "This Is Another Chalmers Year" It was true then, and we repeat it now, for it is more apparently true now than in any other year "This is another Chalmers year."

1912 catalog will be mailed on request.

Chalmers Motor Company, Detroit, Mich.

Simple Patent Law; Patent Office News; Inventions New and Interesting

The Millionth Patent

By William N. Taft

UNMARKED by any pomp or ceremony and with a lack of ostentation that seemed totally inappropriate to the importance of the occasion, the one millionth patent was issued on Tuesday, August 8th.

The wheel of chance which decided the recipient of the epoch-making patent—for the record number was awarded to the patent which happened to be on the top of the pile when the numbering machine passed the 999,999 figure—decided in favor of Frank H. Halton, of Cleveland, Ohio, who had applied for exclusive rights to manufacture and sell an improvement on inflated automobile tires. It was fitting that this patent, in itself a monument to progress, should have been awarded to an improvement on the automobile, for there is probably no single resent invention which has done so much to mark American progress or to show the world the prosperity of the United States.

The presentation of the patent was marked by a most undue democratic simplicity. It was thought at first that there would be no official recognition of the event at all, but Mr. Halton came on from Cleveland to receive the patent at the hands of Commissioner Moore. The fact that the Secretary of the Interior had made plans to tour the reclamation projects of the West during August precluded his attending the presentation of the patent, and he evinced much disappointment at not being able to be present.

The mere statement that the issue of patents has passed the million mark is, in itself, enough to provoke wonder, but a comparison of the number of patents issued in other countries—centuries older than the United States—brings to light many interesting figures. France comes nearest to the United States in the number of licensed inventions, 430,000 being approximately the number of her patents. Great Britain is next with 416,000; Germany has issued 236,000, Belgium, 228,000, Canada, 126,000, Italy and Sardinia, 94,000, and Austria-Hungary, 68,000. All the other countries of the world have issued less than 60,000 patents each, so that the United States may easily be said to have licensed more inventions than any two nations put together, and that her total exceeds that of Great Britain, Germany, Belgium and Italy by several thousand.

Perhaps it is because the "American" is truly a cosmopolite, a mixture of all the bloods of the world, that this nation has so far surpassed others in inventions, but true it is that the majority of the important discoveries of science and the greatest labor-saving machines first saw the light of day in the United States and that the documents granting their inventors the exclusive right to manufacture and sell them are to-day reposing in the Patent Office at Washington.

Among the historic documents in the Patent Office library are the specifications and models for the steamboat, the telegraph, the telephone, the cotton gin, the mowing and reaping machine, the improved automobile, the aeroplane, and countless other machines the invention of which has lightened the labor of the world and improved its method of locomotion, correspondence and living to an almost incalculable degree.

There exists in the Patent Office library at Washington the first patent ever issued in this country, shortly after the close of the Revolution. It is a queer document, this first patent, quaintly worded and with many a turn and twist of chirography peculiar to our forefathers. It was issued to Samuel Hopkins, July 31st, 1790, for a device for making pot and pearl ashes. The archives of the department show that the issuance of a patent in those days was a state occasion. The President and cabinet met in solemn conclave and, after having deliberated upon whether it was proper for the inventor to have the sole right to the manufacture of the child of his brain, presented him with the papers bestowing this privilege upon him. Hopkins was warmly congratulated by President Washington and the event was recorded in all the diaries of those present.

Thus it was for some time afterward. Every inventor had to submit his appeal for a patent directly to the President, and it was acted upon by the entire cabinet. The consequence was that patents came few and far between and the year 1790 saw only three of these documents issued. Besides the one to Hopkins, one was granted to Joseph S. Sampson for the manufacture of candles and the other to Oliver Evans for the manufacture of flour and meal. All three of these were issued and signed by George Washington. Several other patents were issued and signed during the administration of the first President, but the records are not clear as to their number.

Washington, himself a patron of the arts, was liberal and generous in his rulings concerning the issuance of patents, but President Jefferson, fearing that government grants might have the effect of promoting private monopolies, was particularly strict in his censorship of patents.

Dr. William Thornton, an Englishman by birth, and formerly a clerk in the State Department, was the first Superintendent of Patents appointed. It was his duty to see that all the applications for patents were made in the proper form and that it was right that they should be granted. The actual issuance of the papers, however, was still retained in the hands of the President and the cabinet. Dr. Thornton's salary at the time he was first appointed was $1,400 a year. His term of office dated from May, 1802, and lasted twenty-four years.

The Patent Office as it exists to-day was established by an act of Congress of July 4th, 1836, and the first Commissioner of Patents was Henry L. Ellsworth, of Connecticut. It was coincident with the establishment of the Patent Office that the searching system came into vogue. This consists in looking through all the files of the office to see if any patent similar to the one applied for has previously been granted. This had not been done previous to 1836, as no adequate force had been available to perform the work.

The year 1836 also marks the commencement of the present series of patents, numbered consecutively. Before this time 9,902 patents had been issued, but no record had been kept of their consecutiveness. These were, therefore, disregarded in the establishment of a new system and the first patent of this series was awarded to John Ruggles, July 13th, 1836, for a locomotive engine. It is rather a strange coincidence that Patent No. 1 and Patent No. 1,000,000 should both have been awarded to improvements in the foremost modes of locomotion of their times and that these inventions mark the progress of two machines which represent the highest form of power transference then known.

From 1836 to the present time the number of patents issued has been steadily increasing until at the present time it is not unusual to see from 500 to 700 issued during a single week. An example of the enormous increase in the number granted can be found in the fact that Patent No. 500,000—awarded to E. S. Hyde for an improvement on sewerage—was issued on June 20th, 1893—only eighteen years ago! Thus it took fifty-seven years to accumulate the first half million patents and only eighteen years to gather the last half million. Truly is this a wonderful growth, both in inventive ability as well as in recognition of this ability by the government, for in the first two decades of the system very few patents, comparatively speaking, were issued, the Jeffersonian prejudice against government aid of private monopolies not having died.

For each patent issued the government charges a fee of $35—$15 upon the filing of the application and $20 upon notice that the same has been granted, regardless of the length of the specifications or the complexity of the invention. That this charge is extremely reasonable may be seen from the fact that every patent of the million and more stored away in the vaults of the department has to be gone over to discover if the application will conflict with any existing patent, or if the idea is such that a patent cannot be granted on it. This work, through a complicated system of filing, is to-day rendered comparatively easy, though two decades ago it was considered a tremendous task, although the patents were not half so numerous at that time.

From the first Superintendent of Patents in 1802 to the present Commissioner of Patents is a long step. Many changes have taken place during this time, but it is considered that the Patent Office to-day presents an example of a highly specialized and finely organized institution where the papers relating to any patent may be secured at a moment's notice and where there is not much difficulty in discovering whether an invention has been patented before or whether there is any other difficulty in the way of its being patented at the present time.

When the first patent was issued the President of the United States made the grant, as we have seen, while the record was written by a clerk in the State Department. Then followed the Patent Board, composed of the Secretary of State, the Secretary of War and the Attorney General. This was continued until 1836, when the first Commissioner of Patents was appointed, and this office has remained in force until the present day, Edward Bruce Moore being the present occupant of the chair.

Mr. Moore has worked his way up to his present position from the ranks. His first position in the Patent Office was that of Patent Examiner, in 1883, and he has remained constantly in the service of the department from that time to this. Before being appointed to his present position he was sent as a special commissioner to the Paris exhibition of 1900. In 1907 he was appointed Commissioner of Patents and was sent as the special representative of the United States to the International Conference for the Protection of Industrial Property in Stockholm, Sweden, in 1908. He also served in a like capacity at the Fourth International Conference of American States at Buenos Aires, Argentina, in 1910, and was the presiding American official at the recent International Patent Conference, held at Washington.

Notes for Inventors

A Laborer's Fireless Cooker.—A workman in a western city recently made an ingenious application of the laws of chemistry to his own purpose. A few minutes before noon a laborer on one of the big buildings then being constructed, proceeded to heat his coffee for lunch without the aid of a fire or even the use of a match. He took a bottle from his pail, and with it went to the wooden contrivance in which mortar was mixed. He put about half a shovelful of sand in a corner of the mortar-bed, having previously scraped that part of the bed dry and clean. Then he took a piece of lime about as large as his two fists. He pushed the lump of lime down into the yielding sand, put his bottle upright on the lime, banked up the bottle with sand to hold it in position, and was ready for the important part of the work. Dipping about a pint of water from a barrel near by, he poured it on the molded sand easily, allowing it to percolate through the coarse grains. Putting on a little more sand to hold the bottle in position, he went back to his work. In ten minutes the noon whistle blew, and the laborer went to his fireless heater, took from it his coffee, boiling hot, in a bottle that had at no time been in danger of breaking in the heat, and proceeded to enjoy his meal.

The Lure of Invention.—The lure of invention is one that influences all people and spares no class or condition of men. From the clergyman in his study to the convict in his lonely cell, it exerts its attraction, and both are found enrolled among the list of patentees, although not so precisely identified. The stimulus is not always the hope of fee or reward, for we find the millionaire as strongly interested as the very poor. There is something in the attraction that cannot be resisted. Someone has said that writing is like flirting. If you cannot do it, no one can teach you to do it, and if you can do it, no one can keep you from doing it. So it is with invention; no one can teach you to do it, and if you have the divine afflatus, no one can prevent you from exercising it. This is fortunate; for the inventor is subjected many times to discouraging influences in the first instance. Have you ever noticed, however, the pride with which anyone will display an invention even of the simplest character? Surely this is commendable, for we all admire originality, and invention is originality, often of the highest order. While the lure may be regarded apart from the results, we cannot help realizing what a poor world this would be except for the beneficent works of the inventors of all times.

A Swimming Apparatus.—John G. Alfter and Manuel J. Mancos of Oakland, Cal., have patented No. 998,146, a swimming appliance, in which a harness is applied to the swimmer and carries at the back, near the shoulder blades, pivoted paddles which are connected up by means of cords with the legs of the user, so the motions of the legs in swimming will also operate the paddles.

A Cooper Hewitt Patent.—Peter Cooper Hewitt of Ringwood Manor, N. J., assignor to Cooper Hewitt Electric Company of New York, has issued patent No. 998,175, for improvements in the starting and operating of mercury vapor apparatus, in which is employed an hermetically sealed and completely exhausted container with a number of electrodes in it, including an anode and a vaporizable reconstructing cathode with a platinum wire sealed to the wall of the container and lying above and below the surface of the wall of the electrode, with a starting band outside the container with current supplying means and means for applying a momentary high-voltage impulse to the electrodes to accomplish the starting.

Mercury to Weight a Fishing Line.—Fishermen will be interested in a fishing line which has mercury incorporated in its texture in order to increase the weight of the line. The patent is No. 998,341, and was granted to a resident of Bow Skydding, England.

A Self-protecting Check.—A self-protecting check is shown in a patent, No. 998,382, to Arthur J. Fulmer of Grosse Pointe Farms, Mich. The check has a number of separate signature spaces, and a different inking substance for each space.

on the different spaces, so the signature of the drawer of the check on any space will indicate that the amount of the check is not above the amount inscribed on such space.

The Need of Bats and "Billies."—There appears to be a call for better baseball bats and improved batons or "billies" for police use. Only a few weeks ago the property clerk of one of our large cities was complaining of the breaking of the police batons when used upon the head of a resisting prisoner or when rapped upon the pavement, and now Hans Wagner, the popular baseball professional, is quoted as saying "A perfect bat has never been made and never will be." Now he may be right as to what has been, but he is rash in his prediction, for none can say what may be. It is possible that future improvements in the national game may be most pronounced in the equipment of the bats and balls

Wanted: A Sounding Buoy That Will Sound in Still Water.—A sounding buoy which will sound when the water is still would be an important improvement. Such buoys, whether of the bell or whistle variety, are caused to operate by the movement of the water In foggy or thick weather the water is usually still, and the buoys will not be caused to sound. Manifestly, the buoys are more useful in foggy or thick weather than when the weather is clear Some of these buoys are large and heavy, weighing as much as twenty tons, the size and weight being necessary to compress the air for operating whistles whose tubes are sometimes as large as eighteen inches in diameter and for storing the carbide to furnish the gas for the light, the buoys being frequently combination sound and light buoys. While the problem may be somewhat complicated, it does not seem unreasonable to think that a buoy may be provided which will sound by the movement of the water in a high sea, and will also sound when the water is comparatively still

A Woman's Score-sheet for Pivot Bridge.—A woman's interest in bridge is shown in a patent, No 998,167, issued to Alice N. Gardiner of Haverhill Mass for a pivot bridge score-sheet which has two fields, one of which is divided into sections corresponding in number to the number of players, so the names of the players and the totals of the respective players may be placed in the separate sections, while the other field is divided into sections corresponding to the predetermined number of rubbers, each of such sections receiving the score for one rubber and the name of one of the players

A Peculiar Patent Claim.—As an instance of peculiar claims, a recent patent No 998,156, for a blue vat dye, is interesting The first of the claims of the patent reads "The herein described new dyestuffs having *probably* the following general formula," followed by a formula, while the second claim reads "The herein described new dyestuff having *probably* the formula," followed by the formula The use of the word "probably' in the claims seems an unusual one, but possibly the invention was one difficult to define in conventional terms

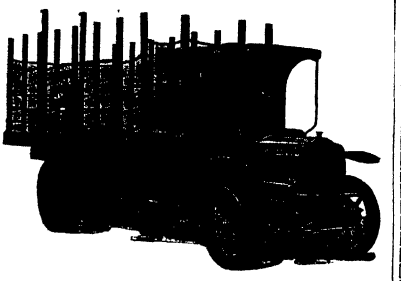
Metal Culverts.—There is considerable activity in metallic culverts, and Charles A. Foster of Portland, Ore., has patented, No 997,382, a culvert structure having a number of culvert sections secured together side by side and in which a transversely corrugated base plate has upturned side flanges and an intermediate flange, and arched top members each engaging the intermediate flange and a corresponding side flange. Mr. Foster has also issued a culvert patent, No. 997,383, including a spiral form of abutment comprising a plurality of complementary corrugated plates which are flanged for connection with the culvert.

A New Knight Patent.—A German automobile paper contains a notice of a new Knight valveless or sleeve valve engine, whose novel feature appears to be in the arrangement of the inlet and outlet ports on the same side of the cylinder and in such position as to open both said ports into the head above the extreme working stroke of the engine We are not aware of the issue of a United States patent for the improvement. The mere opening of both ports into the head appears to be ah wn n the English patent No 16,289, of 1909 although n such patent the ports are located on opposite sides of the cylinder

A Matter of Clothing.—Is there any reason why we Americans, admitted to be the most ingenious people in the world should suffer as our men do in the summer season because of our unreasonable style of dress? Notice a group of men and women in summer while the women are attired in their cotton or linen garments the men will have on coats as warm as those worn by many women in the depth of winter No one has as yet been able to devise or suggest any acceptable summer dress for men, who continue summer after summer to fwelter in warm woolen garments Is this not a fit subject for invention?

A Telephone Repeater —William Anderson of Longdale, Okla , has patented No 997,584, a telephone repeater, in which a repeater is in the telephone circuit and is automatically operative in either direction of transmission The repeater includes two transmitters and two receivers and two inductoriums The transmitters are connected with the primaries of the inductoriums and the receivers being connected with each other are also connected with opposite secondaries of the inductoriums

A Starting and Alighting Gear for Flying Machines.—Matthew B Sellers of Baltimore, Md who has given much time and thought to aviation, has just secured a patent, No 997,860, for improvements in flying machine The machine has a series of planes arranged in stepped form and yieldingly supported at their rear edges and the chassis has both wheels and runners the wheels being held in a relatively low position in starting by means including connections with the draft devices and the wheels are automatically released and lifted after the machine leaves the ground and held elevated relatively to the runners, so the machine may run on the wheels in starting and will alight on the runners



An Edison Phonograph Improvement.—Thomas A Edison has in a patent, No 996 625 provided a new phonograph reproducer seeking to avoid the friction of the stylus sliding over the record by making the stylus in the form of a roller or ball and rotatably supporting the ball so that it will press upon and roll along the record surface The patent also provides a support for the stylus which enables it to rotate with a minimum amount of friction.

Legal Notes

Foreign Words as Trade-marks.—In passing upon the registrability of the Spanish word Elegancia" as a trademark for wine the Commissioner of Patents in *ex parte* Julius Wile, Sons & Company resterates the well-settled doctrine that the foreign equivalent of a descriptive word is not registrable

The Commissioner's Powers Defined — In the case of Cosper v Gold and Gold and Cosper v Gold, the Court of Appeals of the District of Columbia has held that where in an interference involving more than two parties the Commissioner of Patents decides that one of the parties is not the first inventor, such decision is final, but is appealable to the Court of Appeals of the District of Columbia, also that where the Commissioner affirms a decision dissolving an interference on the ground that one of the parties thereto has no right to make the claims, the Commissioner had jurisdiction to enter an order that such party is not the first inventor.

Mandamus and the Commissioner.—The Supreme Court of the District of Columbia by Justice Barnard has just decided in the case of Lang v. Moore, Commissioner of Patents, that where a claim was finally rejected which was not identical with the claim presented, but which the Commis-

Possibilities of Motor Trucks Unlimited

THERE is practically no limit to the possibilities of motor-driven trucks in the business world. Every man who has a cartage problem must feel a personal interest in knowing The White Company have hundreds of trucks in operation in almost every conceivable kind of business—under practically every known condition—and there is not a single owner to whom we could not refer a prospective buyer—not one but has found White trucks to exceed his expectations.

Increased Service White trucks serve their owners, first of all, by increasing the service They make it possible to do things you have never done before—to secure trade you were unable to reach—to be prompt where you were compelled to be dilatory before—to increase your service and thereby increase your business.

Increased Economy Under the majority of conditions, White trucks increase the economy of your delivery—not always—there are conditions where trucks only increase the service. The truck replaces two or three teams—is not as expensive to maintain as two teams and requires no more men to operate than one team, saving salaries

White Trucks—The Solution

White trucks secure these results because they are well designed for economy's sake, having a long-stroke, medium-bore engine, which is powerful while economical. They are built for economy's sake because the best materials modern science has produced is used in them—the special alloys of steel, heat-treated, that are best suited to each of the various purposes to which they are put. White trucks, made in three sizes, with standardized engines in all types, are adapted to any business, any special or unusual requirements.

Let us submit a solution of your delivery problem, with catalogue and testimonials of the world's largest users.

METALLIC DOORS and TRIM
bring forth a powerful editorial from a great newspaper

THE PHILADELPHIA EVENING ITEM

The Phila. Evening Item.

SIXTY-FOURTH YEAR.

"The Paper of the People."

Progress in Fire Protection

Philadelphia, Pa., [illegible]

We are in receipt of a kind letter from the Rochester (N. Y.) Chamber of Commerce, by its President, Albert R. Eastwood, in which we are accorded all the appreciation by that body "of your splendid editorial entitled, 'Public Rising to Prevent Fires' " " That the "Rochester Chamber of Commerce or by that editorial stimulated to carry on this work aggressively, not permanently, for the country at large, but for the results to be obtained within the limits of the City of Rochester.

"If our example will disinfect other communities to like activity, this stupendous fire waste can be somewhat checked."

We reproduce that letter in part as an instance of a popular uprising among the business interests all over the country to reduce our enormous fire losses, losses which the present year shows to be largely on the increase.

In connection with this subject we have just received, with the personal compliments of its author, F. W. Fitzpatrick, consulting architect formerly of United States Bureau, etc., entitled, "Fire and Fire Losses," a handsome work most carefully prepared for instructive purposes.

Mr. Fitzpatrick says fire is the most dreaded of devastators; "it has been used in war for destroying weapons, and in its crude state, so to speak, as an auxiliary which ranks with carnage and rapine.

"In the form of conflagration, it has supplied some of the most spectacular and memorable and saddest events in history."

Mr. Fitzpatrick very properly puts the weight of his argument for fire prevention upon the fire-resisting construction of buildings.

In connection with that conclusion, which is practically unanimous among those who have made a study of the matter, we recently gave considerable time to a consideration of the recent development of using drawn steel in the place of the interior wood work of dwelling and office buildings, and for interior furnishing to both classes of buildings, and for interior railway car work.

To be frank about it, we were greatly astonished at the BEAUTY, STYLE AND FINISH OF THIS STEEL INTERIOR WORK, which is now in use aboard steamships for storerooms and other interior work, as well as in the other cases above mentioned.

This interior steel work cannot be detected by visible inspection. It so closely resembles the finest wood work, both in design, grain, rounded edges, and jointed ornamentations, that the occupant of a room so fitted up would not suspect, were he not told, that he was not surrounded by the finest wood work procurable.

Then, too, this steel interior work is used for practically every purpose—flooring excepted—for no plain woods are used for.

Of course, it is fireproof, will not burn, and overcomes that complaint of fireproof building constructors who have said "How can we make a building fireproof when its occupants fill it up with inflammable furniture?"

For window frames, doors and frames, wainscoting, walls and ceilings, and all interior work this DRAWN STEEL IS MADE AS BEAUTIFUL AS THE FINEST CABINET FINISH OF THE BEST TROPICAL WOODS. And far more beautiful artistic work is possible in shaping this steel than could be worked out in wood.

In fact, artistic designs in this steel as beautiful to-day as they are in study and practice are in their infancy

* * * * * * * * *

The preceding excerpt can give but the faintest idea of the beauty and utility of the Dahlstrom Products.

We are the originators of this class of work and have developed drawn steel construction to its highest efficiency. The Dahlstrom Products are to be found in the structures exemplifying "fireproof reality" such as The Singer Building, New York, William Hunter High School, Philadelphia, First National Bank Building, Denver, Amicable Life Insurance Building, Waco, Texas, U. S. Battleships Florida and Utah, and so on

PEN PERFECTION

The "Swan Safety" Fountpen

Every particle of material used in the manufacture of this pen is of the best possible quality. No expense is spared and each part is separately examined before it leaves the factory.

The patent "LADDER FEED" prevents flooding

The "SCREW - DOWN CAP" prevents leaking

The Pen point is made of 14-Kt. Gold (Iridium tipped) and wears for years.

It is above all quality combined with expert work which has made "Swan Safety" the most perfect pen possible

Why Do You Keep That Corn

Why do you pare it, nurse it, protect it? Why let it torture you? Millions of people simply cover the corn with a little Blue-jay plaster. It is done in a jiffy. The pain ends instantly. In two days the corn comes out.

No pain, no soreness, no inconvenience. No feeling whatever. All because of a bit of soft B & B wax. It loosens the corn while you simply forget it. In 48 hours the corn is gone.

These results are unfailing. They are guaranteed. Five million corns annually are removed in this way. Go get a package—stop that pain. It's folly to have corns.

A is the picture is the soft B & B wax. It loosens the corn.
B protects the corn, stopping the pain at once.
C wraps around the toe. It is narrowed to be comfortable.
D is rubber adhesive to fasten the plaster on.

Blue-jay Corn Plasters

alone decided did not differ in principle or substance therefrom, the Commissioner was exercising his judgment within the discretion and judgment and authority given him, and that the Court cannot in such case compel him to reverse such judgment, even if erroneous, by issuing a writ of mandamus.

The Conservation of Fishery Resources

(Continued from page 185.)

cial and other benefits of oyster culture, as contrasted with the primitive methods that formerly prevailed, should appeal to the few States that insist on doing nothing and are satisfied with letting their oystermen follow the same course that their grandfathers did, regardless of the depletion of the grounds and the neglect of the opportunity to reap large revenue from the sale or lease of barren or exhausted bottoms.

The valuable inshore sponge grounds on the Florida coast long ago became exhausted, and the fishermen were obliged to extend their operations into deeper and deeper water. This condition was brought about by the activity of the operations the demand for sponges, and the indifference of the State. To make bad matters worse, a new destructive element was introduced into the fishery at the most inopportune time for the conservation of the sponge supply. The decline of the sponge fisheries in the Mediterranean Sea, and the interdiction of the use of diving apparatus in some parts of the sea, threw many spongers out of business and resulted in a great influx of Greek divers to the Florida coast. These people have shown no regard for the ultimate welfare of the fishery, and have not hesitated to violate a Federal law for the protection of the industry, so that the present outlook is grave.

In order to make possible the re establishment of sponges on depleted grounds as well as to encourage the raising of sponges as a private enterprise, the Bureau of Fisheries has devised a method of growing sponges from cuttings that is susceptible of commercial application and should be extensively availed of when the State grants to sponge cultivators the proper measure of protection.

The Decline of the Lobster.

In spite of the most active possible hatching operations conducted by the Federal Government at three stations on the New England coast, and notwithstanding perennial attention from the State legislatures the lobster has declined to an extent that causes much concern among those most interested in the welfare of the fisheries. This most valuable of our crustaceans reached the climax of its importance in 1889 or 1890 since which time there has been no interruption to the annually diminishing catch, while the price has steadily advanced. The immediate cause of the decline was the absolute disregard of the lobster fishermen for the welfare of the species. There is no set of fishing laws that has been more systematically, ruthlessly, and unanimously violated than those designed to protect short lobsters and egg-bearing lobsters. These laws have been admirably conceived execrably enforced. There is scarcely a hotel or boarding-house on the entire New England coast that has not had illegal dealings with the lobster fishermen. I have personal knowledge of a State fishery official who encouraged lobster fishermen to bring him short lob sters for his table. I have heard of a United States senator who secretly bought lobsters illegally caught.

Water Pollution.

One of the strongest anti-conservation agencies is the pollution of water by industrial wastes. In thousands of localities insignificant factories or mills have been permitted, if not encouraged, to discharge their refuse into a stream, thereby polluting not only the immediate vicinity but many miles below, and driving out or killing every living thing. What can compensate a community for the fouling of the waters and banks of a beautiful stream or lake? In the long run, a trout or bass stream is of far greater value to a neighborhood than is a mill that pours noxious substances into that stream. This is of course true in the æsthetic sense, but the scientific basis of the controversy, namely, that a polluted stream is a dangerous source of typhoid, food, and recreation to a community. Industrial establishments can and should be conducted without injury to the fishes and other inhabitants of the water-courses on which located. Some of the States have fully recognized this, and have enacted and enforced anti-pollution laws without harm to legitimate business interests; but there is still need for a country-wide crusade against the desecration of public waters and the senseless destruction of useful aquatic creatures.

The Alaskan Fur Seals.

When the Pribilof Islands came into the possession of the United States in 1867 as a part of Alaska, the fur seals thereon, it has been variously computed, numbered from 2,000,000 to 7,000,000, with 4,000,000 as a safe estimate. At the close of the season of 1910 the herd consisted of less than 135,000 seals of all ages. During this entire period the government exercised absolute jurisdiction over the herd while on land, and partial jurisdiction while in the water, and it is therefore the opinion of many people that the government is responsible for the present precarious condition of the herd. This, however, is true only to the extent that the government failed to secure international agreements by which the seals would have received adequate protection while at sea.

It is now universally appreciated that the decline of the fur-seal herd was coincident with and dependent on hunting at sea. The early efforts of the United States government to prevent pelagic sealing in Bering Sea culminated in the arbitration proceedings at Paris in 1893. The award of the arbitration court was against the United States in both of the main contentions, namely, that Bering Sea is a closed sea and that the property right in the seal herd warranted the government in protecting the seals while on the high seas. Since the award of the Paris tribunal, the case of the fur seal herd has gone from bad to worse.

Pelagic sealing is a cruel, wasteful, wholly unjustifiable business that can only be prosecuted in flagrant disregard for or indifference to the question of the perpetuation of the fur seal as a commercial animal. The preponderance of the pelagic catch consists of pregnant mother seals which have left their nursing pups on shore and gone to sea to feed. The killing of every cow seal therefore involves the loss of her unborn offspring and her pup on shore, which inevitably succumbs to lingering starvation, to say nothing of the cow's potential productivity, which may extend over a period of ten years or more. In all of its aspects pelagic sealing is repugnant to one's sense of decency and propriety. Our interests are largest and we have suffered most, but Japan and Russia have also had their herds depleted and almost wiped out by foreign or domestic hunters and raiders.

Notwithstanding that only a remnant of the once mighty fur-seal hosts is left, it is believed that the outlook for the preservation and restoration of the herd is more propitious than at any previous time. This optimistic view is based on the facts that the administration of the seal islands has recently been vested in the Bureau of Fisheries, where the fur-seal service logically belongs, and where it should have been years ago; that the seals are now receiving what they never before had, namely, continuous scientific supervision on which the conduct of the commercial features of the business will depend; and that under the authority and direction of an enlightened Secretary of Commerce and Labor the affairs of the seal islands will continue to be conducted with regard for both seal herd and government, whose interests are necessarily identical.

The most important augury for a new and improved dispensation for the fur seals is afforded by the treaty recently concluded between the United States, Great Britain, Japan, and Russia, by the terms of which the killing of seals on land will be continued at the discretion of the respective governments that are custodians of the seal herds, while all pelagic sealing will be prohibited for at least fifteen years—and let us hope forever.

The Point of Absolute Control

EACH operation of every typewriter part culminates at the Printing Point. The splendid efficiency of the

L. C. Smith & Bros. Typewriter

(Ball-Bearing, Lead-Wearing)

is due to absolute control of all operations as they relate to this exact spot.

Three mechanical features determine the character of work at the printing point—the type-bars, the carriage, and the capital shift.

All these, in the L. C. SMITH & BROS. TYPEWRITER, operate on exactly adjusted ball-bearings, *in a most effective combination of completely controlled forces working together for a perfect result.*

Beautiful, rapid work and a velvety touch, as easy for the operator at the day's end as at its beginning

Ask for a free catalogue and learn about real typewriter efficiency.

Photographs in Railway Work

THE uses of photography are constantly extending. A western railroad has uses for it as a substitute for written reports on construction work For example, the progress of the work of changing a grade crossing or building a bridge is photographed at stated periods, and the photographs are preserved both as a record and as illustrations of method Pictures are also taken of all the resources of the road in the way of material, and of every mile of track, showing curves, grades, switches and crossings A complete set of photographs is used, too, to illustrate the book of rules which is placed in the hands of every railroad man This enables the men to refresh their memories by reference to the view of any particular point on the road, and makes them more readily interchangeable from one division to another The book of rules also contains photographs of trains in more than one hundred combinations of circumstances, and the text informs the trainmen what to do in each case

The "Talking" Picture and the Drama

By Robert Grau

IT was my pleasure to be among those in the audience at Keith's Union Square Theater, in New York, one evening in July, 1894, the eventful night when the motion picture was first revealed to American theatergoers. It is true that an inferior device under the name of Eidoloscope had previously made a feeble effort to introduce, also in a Keith theater (in Philadelphia), the effects which were destined ultimately to change the theatrical map, and to create the most lucrative field of endeavor in the history of public entertaining

The advent of Lumière's cinematograph was announced with much advance advertising, but public interest was not aroused The theater was only fairly filled on the opening night, but an idea may be had of the success from the fact that the theater which had, up to this time, played to average weekly receipts of about $3,000, found its "takings" increased within a single month to the unprecedented average of $7,000 a week, though the cost to the management was probably not over $100 a week for the machine itself

Inside of a year the cinematograph was installed in every vaudeville theater in America, and hundreds of new establishments came into being Thus was inaugurated the vaudeville craze which, as it progressed, brought into being many new devices, such as the Biograph and the Vitagraph In a few years, no theater was without its machine

In 1902 the "store" theater came into existence, and of these there were at one time nearly 30,000 in this country New York city had more than 600 alone An illustration of the vogue of the motion picture is best shown by the statement that one of the earliest endeavorers in this field, Marcus Loew, started in the Harlem district, about five years ago To-day this man is immensely rich. He has about forty theaters of his own, the majority of which are of the first class, such as the American, Plaza, Majestic, Yorkville, and Lincoln Square theaters, in New York Hardly a week goes by that Mr Loew does not add a theater to his list. He has now in the course of erection two magnificent amusement places, involving a cost of nearly a million dollars

About four years ago William Fox, a man yet in his early thirties, opened the first "store" theater in Brooklyn; his success was so great that within a year he had a dozen similar resorts, where moving pictures were the sole attraction. In 1907 this man bought the lease of the Dewey Theater, on East Fourteenth Street, paying a rental of $50,000 a year. He then secured the Gotham Theater, in Harlem, the Star Theater, on Lexington Avenue, and the Family Theater, on One Hundred and Twenty-fifth Street. He also has several theaters in Brooklyn Despite the enormous rentals and the low price of admission, Mr. Fox has made a fortune in the short space of four years, and last year amassed his colleagues by leasing the Academy of Music, paying a rental of $100,000 a year for a building which cost its owners but three times as much

Although Messrs Keith and Proctor have seven theaters of costly construction in Greater New York, but one of these, the Fifth Avenue, is used for the type of vaudeville for which they are supposed to stand; all the rest, including the Union Square Theater, where the cinematograph was first seen, have reverted to the camera man, and Mr Proctor has a score of theaters in the smaller cities, besides those in which he is affiliated with Mr Keith

For several years the various manufacturers of films have been sorely tried to keep up with the demands for new subjects The public patronage has grown to such an extent that millions of new theatergoers have been created To hold this patronage and prevent its being absorbed by the regular theaters, has been the aim of all concerned in this vast industry

Some of the world's greatest players have posed for the film makers, many of whom have stock companies under the direction of famous stage directors and producers.

For several years efforts have been made to create a perfect synchronism between the moving picture and the phonograph, in order that stage presentations of plays and operas could be reproduced

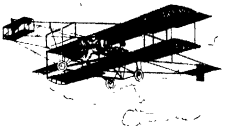
The spectacle has already been presented of a famous stage idol, appearing in a theater of high prices of admission, while but a stone's throw away a perfect counterfeit presentation both as to voice and action could be seen for five cents

Three of the greatest factors in the field of motion photography, including Thomas A Edison, who invented also the phonograph, have announced recently that all of the problems for an absolute synchronism were either solved, or near solution Mr Edison has prophesied that the day is near when the working man will present himself in front of a moving picture theater, deposit his dime, and witness a reproduction of scenes from grand opera, such as are presented at the Metropolitan Opera House in New York

I have already been privileged to hear and see almost an entire act of Donizetti's "Lucia de Lammermoor," including the famous sextette, as sung by Caruso, Sembrich, Plançon and others Although perfection has not yet been achieved, no great wrench of the imagination is necessary, in order to predict that another year or two at most will witness the attainment of absolute synchronism

The serious side of this situation lies in the ultimate fate of the player and singer, and by the same token of the manager and producer

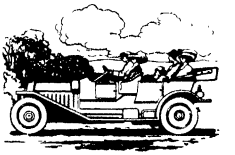
We know that Caruso has earned almost as much money from the preservation of his vocal records as by grand opera. Yet, there are those who have deplored the fact that the penalty is being paid in a slight deterioration in the illustrious Italian's voice



I yield to no one in my appreciation of the benefits to be derived from the phonograph, and have often wished that it had come into being in time to have preserved the voices of Malibran, Jenny Lind and Adelina Patti, in her prime

But if even one year less of Caruso is the penalty which music lovers will have to pay in order that future generations may have preserved for them his vocal records, this price is hard to yield to

It will be of interest to the reader to learn that in Paris such eminent celebrities as Mme Bernhardt Jane Hading, Mme Réjane, and Mounet-Sully have been induced to pose for the moving picture camera One French firm pays fabulous sums, in order that it may raise the level of its achievements

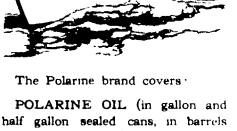


The possibilities of a perfect synchronism in effect of the two great Edison devices (for it must be understood that it was Edison who made possible the motion picture of to-day) are beyond all conception Through this great advancement, the "Passion Play," as presented at Oberammergau, could be brought to our doors, and that, too, at a not very distant date.

It is already on the cards to present before American audiences scenes from grand opera, as presented at the Grand Opera House, in Paris, Covent Garden, in London, and La Scala, in Milan. Thus grand opera novelties, which would probably not be heard in this country for

THE present development of aeroplane and "motors" for land and sea has been made possible by the gas engine

The gas engine has been made practicable through the development of suitable fuel and lubricating oil.



In the production and improvement of these gas engine necessities, this company has always led.

We particularly want to call your attention to our Polarine Oil.

Polarine

This Oil is the product of an elaborate series of special manufacturing processes—many of them devised especially for Polarine.

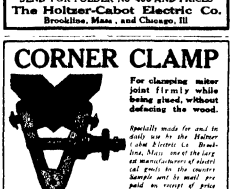
We can safely say that Polarine Oil affords the most perfect lubrication for gas engines of any oil yet produced.

The Polarine brand covers

POLARINE OIL (in gallon and half gallon sealed cans, in barrels and half barrels), POLARINE TRANSMISSION LUBRICANTS, POLARINE CUP GREASE AND POLARINE FIBRE GREASE

These lubricants cover the needs of every part of the car

Send to our nearest agency for "Polarine Pointers" which includes hints on the care of motor cars.



Standard Oil Company

(Incorporated)

years, will have presentations within the year of their European *premieres*; also the great Kiralfy spectacles are now being reproduced, in order that the tremendous barrier of transporting to America over 1,000 persons may be overcome.

The film companies are capitalized in the millions and there is not the slightest indication that any retrograde movement in this field will be permitted.

The great problem which presents itself is the effect that modernism may have on the actual player and singer, but after all, it is the latter element which has made possible the great progress in the moving picture industry, for they are induced to accept the liberal payments offered.

Recently $50,000 was offered to Caruso for the sole right to take his vocal records, and this sum was merely a bonus for exclusive privileges. Mme. Adelina Patti, when in this country on her last tour, *refused an offer of $100,000 for a* similar privilege, and this, too, at a period in her career when she was no longer the Patti of old.

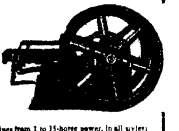
The writer believes that the motion picture theater of the future will be conducted on a far more important basis than that of the present. Already the "store" theater is passing away, and the tendency is to secure regular theaters. In all the larger cities, large and commodious establishments are being erected and millions of dollars of invested capital are available at every turn. The effect on the regular theaters has already been appalling. Two years ago the vast chain of theaters devoted to melodrama found their position untenable, and there are to-day less than a dozen of this class of amusement temples in operation. All have reverted to what is known as "pop" vaudeville, or else they are lying dormant.

In Philadelphia there are two score of handsome theaters, newly built, some costing as high as $500,000 each, and all *created through the really tremendous ex*pansion in the field whereof I write. The attendance is enormous. It is not too much to assert that 100,000 persons attend these theaters daily in the Quaker City. In Boston the situation is quite similar, while in the smaller cities a singular state of affairs has come about. In what are called "one night stands" the moving picture has solved the problem of the local managers who have not hesitated to cast the legitimate attractions to oblivion and turned their "opery" houses into "nickelodeons" and "bijou dreams." Heretofore, the local manager would get one or two companies a week for his public's entertainment, and he had a hard time to pay his way. To-day, by the simple process of installing a moving picture machine and engaging a few minor acts of vaudeville, he is able to entertain from two to three thousand persons each day, at an average price of admission of ten cents. The expenses are small, the profits are huge. I have in mind a little town near New York, with a population of 30,000. Up to two years ago it was impossible to attract a paying audience with anything. To day the one theater available gives three performances daily. Hardly a week goes by that less than 60 per cent of the population does not enter this theater at least once, while it is an absolute normal condition to find as many as 1,000 persons waiting in the lobbies and on the sidewalks, at 9 P. M., for an exodus of the seated audience, so that they may enter and witness the second show.

The public created by this procedure is constantly being educated and gradually becomes more exacting in its demands, hence the advent of the "talking" picture, with all the enhancement which it promises to bring, should result in a general uplift, together with much benefit to the masses who must naturally appreciate any effort which will make possible for them to see and hear for ten cents that which has heretofore cost from fifty cents to two dollars.

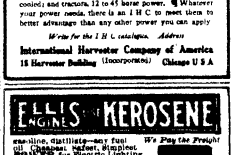
It remains yet to be seen how nearly science and artifice have served to duplicate the original interpretation in music and drama. Mr. Edison has promised that the counterfeit will be almost perfect.

Rubber Bath Sponges



NATURAL bath sponges are becoming scarce and attempts have been made to increase the production by artificial sponge culture. The increasing price of sponges has also led to the invention of artificial sponges made of vulcanized India rubber, which have been in the market for a number of years and are already very largely used. Until recently the method of producing these substitutes, which are remarkably similar to natural sponges in structure, remained the secret of a few German firms, and the efforts of foreign manufacturers to produce rubber sponges were fruitless. It has long been possible to make porous vulcanized rubber, but the imitation of the peculiar structure of the sponge and the production of pores and cavities of various sizes in communication with each other appeared impossible. This object is accomplished in the manufacture of rubber sponges, which is now carried on in other countries than Germany, in the following manner, according to an article in *Caoutchouc et Gutta-percha*. In the preparation of the rubber, certain volatile constituents are added which, in the process of vulcanization inflate the rubber producing an effect similar to that of yeast in bread. Usually a mixture of alcohol and amyl acetate is employed for this purpose. In order to prevent premature evaporation of these very volatile liquids, the rubber is first incorporated with the usual additions, sulphur chalk, etc., and rolled out cold into thin sheets. These sheets are dipped in the mixture of alcohol and amyl acetate and passed again through the rollers. These operations of dipping and rolling are repeated ten or twelve times. The mass is then divided into pieces the size of the fist, which are saturated with a solution of Para rubber and wrapped tightly in silk paper. In this condition the pieces are placed in the vulcanizer, in which the pressure of the steam is allowed to rise to about one half atmosphere in fifteen minutes, is held at this point for twenty minutes, then increased to two and one-half atmospheres and after twenty minutes more is allowed to sink to the pressure of the external air. The sponges are then taken from the vulcanizer allowed to cool in the air, and washed and brushed in water in order to remove the silk paper. They are finally boiled in a two per cent solution of soda and cut up into pieces of the desired form and size. These rubber sponges cannot compete with the finer grades of natural sponges, but they form very good substitutes for the medium and coarser grades.

Summary of the Reclamation Projects



(Continued from page 138.)

been built, so that now, on many streams, no water escapes whatever, and the lower reaches of the river bed have been grown over with trees and vegetation. The reclamation work in this district is scattered over the States of Colorado, Kansas, Nebraska, South Dakota, Oklahoma, and southern Wyoming. In the valleys the rainfall varies from 6 to 16 inches, in the mountains above the project, it reaches as high as 30 and 40 inches. The value of the irrigated lands ranges from $75 to $100 per acre in the northerly projects, to $100 to $1,000 in the southern projects, much of this land having sold for $3 to $10 per acre before the projects were inaugurated. UNCOMPAHGRE PROJECT, COLORADO.—In the Uncompahgre Valley is a body of fine land of 150,000 acres, but the run-off of the Uncompahgre River is limited, and after settlement a succession of crop failures followed. It was found that the run-off of the Gunnison River in the adjoining valley was very large, hence arose the suggestion to tunnel the intervening mountain, and divert the Gunnison River into the Uncompahgre Valley. An attempt was made to do this, but the cost was too great. The Reclamation Service took hold of the work, and completed the tunnel, six miles in length, which has been in use now during the past two seasons. One hundred and forty thousand acres in the Uncompahgre Valley have now an assured water supply, which is to be augmented by building a reservoir on Taylor River, a tributary of the Gunnison. GRAND VALLEY PROJECT, COLORADO.—This project in Mesa County, western Colorado, is designed to irrigate the higher Mesa lands, which include the

PROVED POWER

best and most fertile country. The Reclamation Service has planned a canal which will furnish water to 60,000 acres of irrigable land from the flow of the Grand River. NORTH PLATTE PROJECT, WYOMING AND NEBRASKA—One of the chief water courses in the Middle West is the North Platte River, heading in the high mountains of Colorado and flowing through Wyoming and Nebraska on its way to the Missouri. Although its flow is large during the spring months, it goes practically dry during the later summer months, and is generally limited in flow after July 1st. To conserve these waters, a large dam 218 feet in height has been built to form the Pathfinder Reservoir, which has a capacity of over a million acre-feet, and will irrigate some 350,000 acres in Wyoming and Nebraska. The first unit, comprising 117,000 acres, is nearing completion, the second, comprising 80,000 acres, will shortly be started, and the third is now under investigation. BELLE FOURCHE PROJECT, SOUTH DAKOTA.—Surrounding the Black Hills in South Dakota are situated numerous bodies of land of more or less limited areas, which would be fine farming land if there was sufficient moisture; but as the rainfall is below what is needed to produce crops, these areas are practically unoccupied and of very little value. The Belle Fourche Project, nearing completion, stores the water of the Belle Fourche River in a reservoir which will have a capacity of 200,000 acre-feet of water, and will conserve about 100,000 acres of irrigable land. The water is diverted into the reservoir from the river by a canal 70 feet wide and 10 feet deep. From the reservoir two large main canals carry the water to the land, from which lateral canals distribute it to the farms.

Brooks Comet of 1911

THIS comet, discovered by Dr William R Brooks at Smith Observatory, Geneva, N Y., on July 20th, has been observed on every clear night by its discoverer, and at many other observatories throughout the world. On August 9th it was about seven degrees north of the star Beta in the constellation Pegasus, from which point the comet is moving northward about one degree daily.

Three of Prof Brooks's previous comets have been found in Pegasus—he has discovered twenty-six comets in all—so that this constellation seems to be a favorite hunting ground for the Geneva astronomer. The following elements of this comet have been computed by Mr Young and Miss Aitken at the Lick Observatory:

PERIHELION PASSAGE, OCTOBER 27TH, 1911

	Deg	Min
Perihelion minus node	153	25
Longitude of node	282	53
Inclination of orbit	33	45
Perihelion distance	0 482	

The comet is coming nearer and growing brighter, and promises to be an interesting object. It is now visible in a moderate-sized telescope, and will be observable for several months.

Motor Omnibuses in War

THE German military maneuvers this year will, as usual, possess many interesting features affecting modern warfare. It is anticipated that motor omnibuses will play a very great part in the maneuvers.

Each motor omnibus will be provided with room for fifty soldiers and possess a speed of about twenty-six kilometers an hour. This experiment was tried with a small portion of troops last year in Germany, and was found to work splendidly, the men being conveyed to the desired positions far quicker than if they had marched on foot, in addition to reaching their destination much fresher and readier for the work before them.

This year, when a long march is occurring, it is intended to use the motor omnibuses in conjunction with foot marches. The buses will convey a portion of the troops ahead, drop them at a certain point, whence they will continue their march, refreshed with the rest and the drive, and the buses will return to the main body for another load of soldiers, who will, in turn, be conveyed to the new advanced guard.

Costly Mining

IT might be said that in these days gold mining is about as expensive a way of making money as one could devise.

It is often necessary to put a fortune into the ground before one can begin to take out a bit of the gold. This is especially true of hydraulic mining. The largest hydraulic gold mine in the world is that in Trinity, California. There the owners are engaged in tearing away great sections of Oregon Mountain with immense streams of water. Now, to dislodge hundreds of tons of earth, and to roll immense boulders about as if they were marbles, requires, it is needless to add, a great force.

The operations at the Trinity mine extend over an area of between 2,000 and 3,000 acres. It was demonstrated from the first that gold was present in paying quantities in this mountain, but the difficulties in the way of getting at it were very great. There was no water available in the vicinity of the proposed mine, and water—a lot of it—was necessary. So it had to be brought through a pipe line from a point thirty miles away. A part of this line goes through a tunnel in the side of a mountain. This tunnel is a mile and a half long and its construction consumed a period of two years. The water is forced into a huge reservoir on the top of Oregon Mountain, and is conducted from this to the nozzles of the hydraulics.

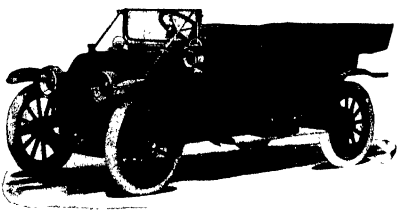
From one of these nozzles a stream eight inches in diameter rushes out. The dislodged earth is carried through races and sluices prepared to receive it. Nearly 10,000 cubic yards of earth are turned into these sluices every day. Once a month the sluices are drained of the water, and the gold is gathered. Its weight carries it to the bottom of the heap. The gold obtained at these monthly intervals ranges from $15,000 to $40,000 in value.

As the mine is about fifty miles from a railroad, one can easily understand how great is the expense of transporting machinery and supplies. The cost of the tunnel and pipe line, too, was large, so that, before a dollar's worth of ore was taken from the mine, quite a fortune had been put into it. The present system is not much like that of the early days in California, when one or two men started out to seek a fortune armed with nothing but picks, shovels and pans. The returns on mining investments in these days, although in some cases good, are no greater than in many manufacturing concerns.

Spiders' Threads in Astronomy

THE cultivation for scientific uses of certain species of spiders, solely for the fine threads they weave, has an important bearing upon astronomy.

No substitute for the spider's thread has yet been found for bisecting the screw of the micrometer used for determining the positions and motions of the stars. Not only because of the remarkable fineness of the threads are they valuable but because of their durable qualities.



The threads of certain spiders raised for astronomical purposes withstand changes in temperature, so that often in measuring sun spots they are uninjured when the heat is so great that the lenses of the micrometer eyepieces are cracked.

These spider lines are only one-fifth to one-seventh of a thousandth of an inch in diameter, compared with which the threads of the silkworm are large and clumsy.

Turbine Water Meters

IN the *Revue de Mecanique*, Mr. Dariès publishes a detailed monograph on turbine water meters, or so-called speed meters, these are somewhat less sensitive, but, on the other hand, cheaper than those of disk construction.

The turbine water meter consists essentially of a vertical shaft provided with blades, and contained in a chamber into which the water is admitted through oblique orifices. The momentum of the water sets the shaft rotating, and a system of toothed wheels connected to an indicator registers the number of turns

Haynes 40 Close-Couple, Model 21, 4-passenger, $2100, fully equipped

Haynes 40 Limousine, Model 21, electric and oil lighted, $2750, fully equipped.

Haynes 40 Colonial Coupe, Model 21, electric and oil lighted, $2850, fully equipped

Haynes 50-60 Touring Car, Model Y, 7-passenger, $3000, fully equipped

Haynes 50-60 Fore-door Limousine, Model Y, electric and oil lighted, $3800, fully equipped

All models are so designed as to accommodate dynamo electric lighting equipment, which we will install for purchasers at nominal cost.

THE 1912 Haynes car, product of America's oldest and most experienced automobile manufacturers, is bigger in every way, more powerful and more pleasing in its lines than any of its predecessors. The time-tested sweet-running Haynes motor has been built with greater stroke and bore, giving more power, greater flexibility and decreased vibration. The wheel base has been lengthened. The brakes are larger, providing 1 square inch braking surface to every 13 lbs of car. And with these improvements there are many refinements in style, such as the rich black body and running gear, with black enamel and nickel trimmings throughout.

The 1912 Haynes is now ready for delivery. You can see the new models at our branches and agencies, or we shall be glad to send you a catalogue and name of nearest dealer.

SPECIFICATIONS HAYNES MODEL 21

Motor, 4 1/8 inch bore 5 1/8 inch stroke 7 head Haynes type cylinders cast in pairs offset 1 in Trunnie four point suspension. Wheel Base, 130 inches. Ignition Remian dual magneto with dry cells for starting. Carburetor, Stromberg 1 1/2 in. Model B. Lubrication Splash and force feed oil reservoir in lower half of crank case and filled through breather pipe in dealer of crank case. Steering Column Worm and gear type Timken roller bearings on shaft corrugated hard black rubber rim aluminum spider, 18 in. wheel. Clutch, Haynes contracting steel band on bronze drum Supported by crank shaft Easily adjusted and lubricated. Transmission Selective type three speeds forward one reverse. Timken roller bearings. Rear Axle Timken full floating type pressed steel housing supporting full weight of car. Shaft, alloy steel. Front Axle Single piece I beam 3 inch drop forged Spring seat forged integral Spindles 1 16 inch Diameter Timken roller bearings. Wheels, Artillery type wood, twelve spokes front and rear Rims spoked alternating in rear wheels. Tires, 36 x 4 inch front and rear Demountable rims. Springs, Front semi elliptic 40 inches long 2 inches wide 6 leaves Rear, 42 1/2 inches long 2 inches wide 6 leaves Fitted with grease cup both front and rear. Brakes, Internal and external on rear wheels. Drum is 12 1/2 x 3 face. Lining, Raybestos 1 inch 18 rivets of paint all hand rubbed. Wheels black enamel body All metal equipment, gun metal black enamel and nickel. Equipment, Remian dual magneto Stromberg Model B Carburetor with Rushlight, wind shield, Pyrene fire tank, five lamps Warner 60 mile dial speedometer extra Borrian Kenosheet adjustable, Tanner automatic gasoline gauge.

NEW YORK—1715 Broadway Dept. E. KOKOMO, IND. CHICAGO—1702 Michigan Avenue

DON'T BUY GASOLINE ENGINES

Until you investigate "THE MASTER WORKMAN," a two-cylinder gasoline, kerosene or alcohol engine, superior to any one-cylinder engine; revolutionizing power. Its weight and bulk are half that of single cylinder engines with greater durability. Costs Less to Buy—Less to Run. Quickly, easily started. Vibration practically overcome. Constantly mounted on any wagon. It is a combination portable stationary or traction engine. SEND FOR CATALOGUE. *THE TEMPLE PUMP Co., 417 West 15th Street, Chicago.* THIS IS OUR FIFTY NINTH YEAR.

"MACK" The LEADING GASOLINE TRUCK of AMERICA

THE "MACK" is the result of seven years of centralized effort in the production of motor trucks exclusively. That is why the largest and most progressive firms in America are installing "MACK" motor transportation service after trying out and experimenting with various other makes of trucks.

The illustration shows the case of operation with which the "MACK" delivers seven tons of gravel, sand, lime or other material at one load. With rapid loading facilities, this truck is capable of handling 150 tons per day at a maximum cost of 15 cents per ton per average of two miles.

Our handsomely illustrated catalog, shows over 100 "MACK" installations; details of each, and other valuable information which every prospective truck buyer should know. Mailed free. Write to-day.

Notes and Queries

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12511) W T H writes: In your Answers to Correspondents, No. 12470, it is stated that steel is compressible at the rate of 68 millionths per atmosphere of pressure. I have the apparatus to make a simple test of the matter, a cylindrical tank, of sheet tin, 12½ inches in diameter with cone-shaped ends, having a capacity of about three cubic feet. The "tin" does not exceed 1/64 inch in thickness. My proposition was to pump 15 pounds per square inch air pressure into the tank and observe the increase in the girth when the pressure was on. I figured that if steel (or iron) was compressible (or extensible) at the rate mentioned, the girth of the tank should be 3/8 of an inch greater when the pressure was on. I made the experiment three times. The first time there was apparently an elongation of about 1-16 inch. The second and third times I used more care, keeping the tape measure in the same position and keeping it close to the same tightness in all the measurements. In the two last trials there was no observable difference in the girth before and after the pressure was on. Of course extensibility is not compressibility, but I assume that they are about the same in amount, only in opposite directions. The experiment seems to indicate that there is no appreciable extension of iron with a tensile strain of nearly 7,000 pounds per square inch. Are my figures right or 68 millionths in volume per atmosphere of pressure tells nothing of the deflection in one direction only under a strain. The coefficient of elasticity of steel is 30,000,000, which means that one pound per square inch tensile stress will elongate the steel 1/30,000,000 of its length. Using the formula $pd \div 2\ 7S$ for your experiment $15 \times 12½ \div 2 \times 1/64 \times 6$ and $S = 6,000$ pounds per square inch on the cross-section of the trimmed iron, 1/64 inch thick. This would elongate the circumference of the tank $6.000 \div 30,000,000$ or $1 \div 5,000$ of its $12½ \times 3.14$ length around, equal to $\frac{37.5}{5,000}$ or 0.00785 inch—too small to measure. Evidently the seam of the tank yielded in the first experiment, and after the butt-motion was taken up you obtained no appreciable effect from the 15 pounds pressure again applied.

(12512) S E K says: 1. Is there such a thing as "heat" lightning, or is all lightning "chain" lightning, and what we call heat lightning simply the reflection of a distant thunder storm on the clouds? A. The lightning called "heat lightning" is usually due to the reflection of a lightning flash below the horizon upon clouds above the horizon. It is too distant for one to hear the thunder from the flash. All lightning is not "chain" lightning. The real existence of "ball" lightning is now quite generally admitted by men of science. 2. When we see oblique rays apparently coming from the sun, is this really the action of the sun "drawing water," as the saying is? A. The appearance which is called "the sun drawing water" is caused by the sun's light passing through openings in the clouds and illuminating the particles in the air below, thus producing light streaks in the space below. The same may be seen sometimes after the sun has set, the stripes there being directed upward.

(12513) A W K asks: Will you kindly inform me through your Question Column of a good formula for wet cells? A. There are four principal forms of wet cells, the one to be used depends upon the character of the service required. For interrupted, occasional work such as bells, burglar alarms, and igniting gas and gasoline engines, the Leclanche cell is the best. Its solution is made by dissolving a quarter of a pound of ammonium chloride in water, enough for one cell. The Edison cell is also used for ignition and similar purposes. Its solution is a rather strong solution of caustic potash. The proper quantity is furnished with the cell. For a steady, constant current, such as is required for electroplating charging small storage cells, or for a telegraph battery, the gravity cell is the best. Its solution is a saturated solution of copper sulphate in the copper plate in the bottom of the jar with crystals of the same salt in excess to maintain saturation. And last for giving a large current for a short time, such as for heating a wire coil, running a motor or working an induction coil for X rays or a small wireless telegraph outfit, the best cell is the bichromate cell. The solution is a strong solution of bichromate of potash in sulphuric acid and water. The mode of preparing the solution as well as of making the battery is well described in SUPPLEMENT No. 702. A full description of all these cells is contained in SUPPLEMENT Nos. 157, 158, 159, which you should have if you need to use wet cells for any purpose. We will send the four papers for forty cents. Wet cells are not much used. The more convenient dry cell has taken their place. The dry cell is simply a Leclanche cell in which the solution is absorbed in some material so that it will not run out. The cell is then sealed to prevent evaporation.

(12514) E F B says: Can you tell me approximately how many vibrations per second are required to produce a sound so high in pitch that it would be imperceptible to the average human ear? A. The average range of hearing is from 16 to about 40,000 vibrations per second. Some persons are not able to connect 16 vibrations per second into a continuous tone, and for some the inability to hear is below 40,000. This matter is tested by a Galton's whistle, which can be tuned up to more than 40,000 vibrations.

(12515) J D asks: A filled a drinking glass full of water, placed a piece of paper over the top, held it firmly, reversed the glass paper side down, then removed his hand from the paper, the paper remained in its place, and the water did not run out of the glass. A says it is due to the atmospheric pressure on the outside. B says it is vacuum and atmospheric pressure. Which is correct? A. The experiment you describe is explained by the surface tension of the water, which prevents the air from entering between the paper and the upper edge of the glass, and the atmospheric pressure, which holds the paper up and prevents it from dropping off the glass. It is not necessary to have the glass full of water if only partly full, with air above the water, the experiment succeeds just as well. No vacuum is formed.

(12516) F D D asks: The Nautical Almanac states that June 21st (astro day) is the longest day of the year, being 15 hours 23 minutes 0'60 W longitude, 43 N latitude), but the earth does not reach aphelion until July 2nd on which date the day is 5 minutes shorter than June 21st. I have always supposed that the axis of the earth tipped toward the sun to its greatest degree on June 21st, and consequently the earth must be at aphelion on that date. A. The sun is longest above the horizon on June 21st or 22nd and hence this is the date of the longest daytime, or, as we term it in common speech, "the longest day." This is because the sun is then farthest north. It is vertically over the Tropic of Cancer, and makes the longest daytime in the northern hemisphere and the shortest daytime in the southern hemisphere. There are more degrees of the diurnal are above our horizon in June than in January or any other month of the year in the northern hemisphere. This does not depend upon perihelion at all. The earth is in perihelion on January 1st to all parts of the earth alike, and in aphelion early in July. At perihelion the earth is traveling swiftest in its orbit, and at aphelion it is moving slowest. At perihelion the sun therefore makes more right ascension between noon and noon than at any other time of the year. For this reason the time from noon to noon is longest, more seconds, on January 1st. This you can easily verify by the Nautical Almanac. January 1st is the longest day, from noon to noon, in the year. From this you will see that the longest day is a very different idea from the longest daytime. The longest day nearly coincides with the shortest daytime in the northern hemisphere but in the southern hemisphere the longest day and longest daytime are nearly coincident. The two are determined by different conditions, and are not dependent upon each other at all. The axis of the earth is for limited periods in positions parallel to itself. At the equinoxes, March and September, the sun is vertical over the equator, and the axis of the earth makes a right angle with the line joining the centers of the earth and the sun. At the summer solstice of the northern hemisphere in June, the earth's axis has come around apparently, so that its northern end is directed 23 degrees 30 minutes over toward the sun. The converse of this is true of the southern hemisphere at the same time. At the winter solstice of the northern hemisphere the axis of the earth has shifted 47 degrees from its position as referred to the sun from what it occupied at the summer solstice. A small globe, even an orange, and a lamp will enable you to demonstrate all this experimentally. It is nicely described in Todd's "New Astronomy," pages 150 to 160, a book which we send for $1.50 postpaid. Our circulation takes the Scientific American all over the world, and a description of these phenomena written for the northern hemisphere would be the reverse of true for the southern hemisphere.

(12517) R J G asks: Does an exhaust fan create a vacuum when running at full speed? A. An exhaust fan creates a partial vacuum only. It cannot draw all the air out of a room or space. The very best mechanical air pump cannot do that.

A PLAN for INVESTORS
We invite your inquiries regarding our plan for the purchase of Railroad and Industrial Stocks, whereby WE COMBINE Higher Income, Increase in Value, Absolute Safety, on purchases of active listed securities.
We will send you upon request description of this plan, which is superior to buying stocks upon partial payments without eliminating partial payment advantages.

NEW BOOKS, ETC.

HOME VEGETABLE GARDENING. By F. F. Rockwell. Philadelphia: The John C. Winston Company, 1911. 16mo.; 262 pp.; illustrated. Price, $1 net.

Instead of treating his subject in the usual encyclopedic manner, the author, himself a practical gardener, has endeavored to tell the man with a suburban lot how to put in a successful vegetable garden, and the things which such a man would wish to know are told in some kind of natural sequence, that the knowledge may be acquired and utilized to the greatest advantage. The area necessary for families of various sizes is given, the best way to apportion the space to the vegetables grown, and the varieties most easily and profitably raised, with the most approved methods of planting, cultivating, spraying, and fertilizing. Fruits and berries are given considerable space, and a strong argument made for the growing of them. Sixty four pages of illustrations brighten and improve the work. We note that the only index is by chapter headings. A detailed index would have been an appreciated and useful feature.

HAND BOOK OF GASOLINE AUTOMOBILES. New York: Association of Licensed Automobile Manufacturers.

This catalogue illustrates in the best possible style upon fine coated paper the machines made by those firms which make up the Association of Licensed Automobile Manufacturers. Touring cars, roadsters, runabouts, trucks, power wagons, every conceivable type of gas-propelled vehicle is here pictured with its specifications appended. This is the eighth annual announcement of the Association of Licensed Automobile Manufacturers, which now comprises seventy-nine makers and five importers.

THE ELEMENTS OF MACHINE WORK. By Robert H. Smith. Boston: Industrial Education Book Company, 1910. 8vo; 192 pp., 204 illustrations. Price, $2.

In the matter of text books our students of mathematics, physics and chemistry are better provided for than are our students in technical and trade schools and our shop apprentices. "The Elements of Machine Work" takes the learner through the processes of laying out work, chipping, filing, and scraping, hardening, tempering, and testing of steels, pipe fitting, soldering, and brazing, aligning shafting and installing machines. The matter is condensed but none the less careful and eminently practical. Not technical students alone, but every youth who runs a lathe or uses tools as a hobby, may benefit by adding this text book to his working library.

THE GYROSCOPE. By V. E. Johnson, M.A. New York: Spon & Chamberlain, 1911. 12mo.; 52 pp. Price, 60 cents.

This is a brochure setting forth the principles and behavior of gyroscopic toys, from the spinning top to the monorail car. It abounds in instructive experiments, gives plans for the construction of a model car with various methods of drive and a special form of contact planes, and has a final word to say in behalf of other stabilizing systems and their probable utility in combination with the gyroscopic method.

QUESTIONS AND ANSWERS FOR AUTOMOBILE STUDENTS AND MECHANICS. By Thomas H. Russell, A.M., M.E. Chicago: The Charles C. Thompson Company, 1911. 8vo.; 140 pp.

The questions progress in logical order from basic principles and the main features of construction and operation to accessories, details, and varying methods. The catechism differs somewhat from most guides of similar form, in that the answer does not immediately follow the query. Instead, there is a chapter of numbered questions followed by a chapter of correspondingly numbered answers. This facilitates the use of the questions as a review test, yet places the answers within easy access in case of need. A drawback of the catechism is its entire lack of illustration. This somewhat quits it for the use of the absolute novice unless supplementary words and diagrams are at hand. It is particularly designed, however, for school teaching, for the machine shop, or before the board of examining engineers. For any of those purposes it is well conceived and covers the field in a commendable manner.

MECHANICS FOR ENGINEERS. A Text-Book of Intermediate Standard. By Arthur Morley, M.Sc. New York: Longmans, Green & Co., 1910. 8vo.; 280 pp.; illustrated. Price, $1.20.

As a text-book, this is meant to fill a need brought about by the fact that the requirements of students in engineering are not identical with those of the student in general science. Since engineering students constitute a large proportion of the enrollment for mechanics classes in technical schools it is only right that they be provided with a course which recognizes their special needs. The author adheres to the gravitational system of units, defending it on practical grounds and pointing out that with proper premises it is just as rational as the "poundal" system which is confined to school work and must be discarded upon taking up practical problems in engineering. It is assumed that the reader is familiar with algebra to the progressions, the elements of trigonometry, and curve plotting. The calculus has not been used. The course laid down should easily be completed in a year.

INTRODUCTION TO GENERAL CHEMISTRY. By John Tappan Stoddard, Ph.D., New York: The Macmillan Company, 1910. 8vo.; 432 pp. Price, $1.60 net.

The information here given is graded and arranged with a view to its use as a first-year course in chemistry. The importance of sound reasoning from experimental results is recognized, and much of the work given is of a nature to induce in the student the true scientific attitude combined with enthusiasm and judgment. There are no pictorial illustrations, the writer arguing that the class room or laboratory furnishes sufficient concrete examples in apparatus, while confusion is apt to arise when the drawings of a text-book differ in general form or in detail from the actual experimental apparatus used.

GOOD ENGINEERING LITERATURE. What to Read and How to Write. With Suggestive Information on Allied Topics. By Harwood Frost. Chicago: Chicago Book Company, 1911. 8vo., 422 pp.

Assuming that every engineer is sooner or later called upon to do some form of literary work, Mr. Frost essays to instruct the engineering fraternity in the art of written expression—in the preparation of reports, specifications and contracts, and of descriptive papers for technical societies and periodicals. A few rules in grammar and orthography are given, but the instruction is mainly confined to imparting such knowledge as will result in the clear and forcible description of works and ideas. The author is not only a successful maker of books himself, but was formerly editor of *The Engineering Digest*, and the work is full of the most condensed and valuable information which readers and writers of technical subjects would be benefited in learning. There are chapters on collecting and arranging material on exercising the memory, on the preparation of manuscripts, the "field" and "policy" of technical journals, and "the making of a book."

POLAR EXPLORATION. By William S. Bruce, LL.D., F.R.S.E. New York: Henry Holt & Co., 1911. 12mo.; 256 pp. Price, 75 cents net.

There is a peculiar fascination about polar adventure that seems to be in inverse ratio to its rigors and loneliness. Dr. Bruce, with nine expeditions to his credit, recounts in simple, forcible English the facts of which keen and extended observation has made him master. He begins by stating astronomical facts that the reader should know, that the polar days and nights are each of six months duration, that it is always noon at the pole, whether light or dark, although there are alternations of seasons, that the sun describes an ascending spiral during one season, and a descending spiral at another. Having seen that the reader forms a right conception of these conditions, the author proceeds with description and comment until he has packed between the covers of his little book pictures of Arctic sea and ice, observations on coloration, and on plant and animal life, and thrilling incidents on ship and foot. As the volume is in adventure, its chief claim to attention is in showing the aims of polar exploration in its relation to science and biology. A work of greater length and importance is promised.

THE EVOLUTION OF PLANTS. By Dunkinfield Henry Scott, M.A., LL.D., F.R.S. New York: Henry Holt & Co., 1911. 12mo., 256 pp.; illustrated. Price, 75 cents net.

"The Evolution of Plants" is an attempt to tell "the story of the development of flowering plants, from the earliest geological times, hitherto locked from technical language." Dr. Scott restates in brief the Darwinian theory, afterward dealing at considerable length with the problem and the evidence. There are chapters on the evolution of the seed plants, of the ferns, and of the higher spore plants. The story concludes with deductions drawn from the fossil record as compared with the organisms of existing plants, from the likeness between fern and seaweed, from the consistency between the thallus-theory and the fossil record, and with theories of a more general kind based upon the known facts. A few errors which have escaped the attention of the proofreader do not materially affect the popular value of the book.

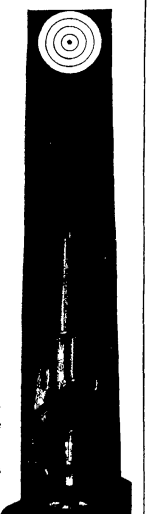
SECOND COURSE IN ALGEBRA. By Herbert E. Hawkes, Ph.D., William A. Luby, A.B., and Frank C. Touton, Ph.B. New York: Ginn & Co., 1911. 12mo.; 264 pp.; illustrated. Price, 75 cents.

The course as laid out includes all the topics necessary for entrance to college, and is particularly adapted to students whose second year in mathematics has been devoted to geometry. The first part of the course is a very thorough review, leading up to the advanced material in which the best methods, new or old, are employed. Graphs are utilized in an ingenious manner in connection with logarithms, and all the exercises and problems aim to present new and varied material in an appealing way.

Dependability
Accuracy
Safety

are the three cardinal points in PERFECT revolver construction

From a scientific standpoint the



SUPERIOR

Smith & Wesson

REVOLVER

represents the **maximum** of perfection. Its worth has been attested by satisfied users all over the world.

It has brought the winning score in practically every national championship. For over half a century it has safeguarded the life and property of a people.

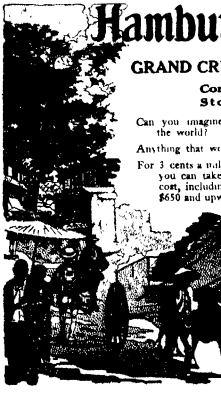
GRAND CRUISE AROUND THE WORLD



Conserve Your Good Health!

Store Up New Energy!

Can you imagine anything more enjoyable than a trip around the world?

Anything that would do you more good?

For 3 cents a mile or $6.00 a day, a mere transportation charge, you can take this wonderful trip, lasting 110 days, at a total cost, including all necessary expenses afloat and ashore, of from $650 and upward according to location of state room.

Two cruises on the magnificent S.S. Cleveland (17000 tons) from New York, October 21st, 1914; from San Francisco, February 6th, 1915.

The itinerary includes Madeira, Spain, Italy, Ceylon, Straits Settlements, Java, Philippines, China, Japan, Sandwich Islands, in Overland American Tour, Inland Excursions, and Side Trips.

97 days in India 14 days in Japan

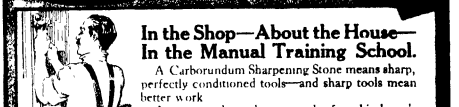
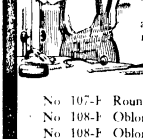
IF you've built air castles about what a real smoke is, let them come sailing down to earth and harden into granite, for here's



Philip Morris English Mixture and Cut Plug



Every pound of "P M" costs you $2.00, but it's worth it We could tell you a long story about the supreme quality of the leaf, how we have produced tobacco for you that's fit for a king, but if you've sworn out a search warrant for pipe consolation, chance a quarter for a trial tin. Let the smoke be the perpetual orator.

Most all good shops sell Philip Morris English Mixture and Cut Plug in 25c. 50c and $1.00 tins. If yours doesn't, send us his name and address with 25c for trial tin of either brand

PHILIP MORRIS & CO., Ltd.
413 West Broadway, New York City

CARBORUNDUM
Sharpening Stones

In the Shop—About the House—In the Manual Training School.

A Carborundum Sharpening Stone means sharp, perfectly conditioned tools—and sharp tools mean better work

Any man or boy who uses tools of any kind needs a Carborundum Sharpening Stone—the most remarkable sharpening agent ever discovered

Hardware dealers everywhere sell them, if yours doesn't, send direct—don't be satisfied with an inferior stone.

No 107-F	Round combination stone for carpenters	$1.00
No 108-F	Oblong combination stone	1.25
No 108-F	Oblong combination stone in aluminum box	2.75
No 109-F	Scythe and grass hook stone	.25
No 114-F	Sportsman's pocket stone in soft leather case	.75
No 149-F	Pocket stone in cardboard case	.15

Science

Return of Wolf's Comet.—We read in *Cosmos* that Prof. Max Wolf himself has re-located, on the 19th of June, the comet which is known by his name. Its position on that date at 12 h. 4 m. 9 s. (mean Koenigstuhl time) was R. A. 18 h. 46 m. 16 s. Dec. 13 deg. 23 m. N. The brightness was equal to that of a star of the fifteenth magnitude, so that the comet was just visible in large instruments This periodical comet takes 6.823 years to complete its orbit It passed its perihellon on May 4th, 1905, so that it is due to return there in the early months of 1912; its distance from the sun will then be 1.095 (refer to the earth's distance from the sun as unity); its aphelion the comet recedes to a distance of 5.689.

The Ivory Supply.—In view of the rapid disappearance of the herds of elephants which formerly roamed in Africa, and the limited number of those animals remaining in Asia, attention has been called to the enormous supply of ivory which exists in the frozen tundras of Siberia, and which, it is thought, will probably suffice for the world's consumption for many years to come. This ivory consists of the tusks of the extinct species of elephant called mammoths. The tusks of these animals were of great size, and are wonderfully abundant at some places in Siberia, where the frost has perfectly preserved them, and in many cases has preserved the flesh of the animals also

The Intrinsic Light of the Stars.—According to *L'Astronomie*, M. Nordmann, of the Observatory of Paris, has made some interesting calculations of the intrinsic light of a number of stars, based on the results he had previously attained in regard to their effective temperatures The brightness of a star, as seen from the earth, does not depend wholly upon its size and distance Thus M Nordmann finds that Sirius and Vega emit *light* the brightness of which is six million candle-power per square centimeter, while at the other end of the scale the light of Aldebaran amounts to only 22,000 candle-power per square centimeter The intrinsic brightness of Vega is, according to this calculation, nineteen times that of the sun If Vega were of the same size as Aldebaran and at the same distance from the earth, the former would appear to us over two hundred times as bright as the latter

Queen Ants and Queen Bees.—It is claimed that the queen ant has not had justice done her by naturalists. As compared with the famous queen bee, she is regarded by Doctor William Morton Wheeler as a far more admirable creature In fact, they are, in many important respects, diametrical opposites. The queen bee is, it is pointed out, a degenerate creature, unable to nourish either herself or her young, to visit flowers, to build combs, or to store them with honey. With the queen ant quite the reverse is true. She is held to be a perfect exemplar and embodiment of her species, and the worker ants suffer from incomplete and retarded development The queen ant is a very industrious and intelligent worker, and, in the opinion of the authority mentioned, she forms an exceedingly interesting subject for study, and has not hitherto been well understood.

The Australian Antarctic Expedition.—Dr. Douglas Mawson, of the University of Adelaide, recently addressed the Royal Geographical Society, in London, outlining the plans of the expedition which will leave Australia under his command about the end of this year. The object is to explore the long stretch of coast known as Wilkes Land, lying between Cape Adare and Gaussberg (Kaiser Wilhelm II Land). Several parties will be landed at various points. The expedition is being recruited chiefly from graduates of the universities of Australia and New Zealand, and every member of the land parties will be a specialist in some branch of science A visit to the south magnetic pole is part of the programme. From a geographical point of view this undertaking appears likely to yield the most interesting results of any of the Antarctic expeditions now projected or in the field.

Electricity

Electric Contact Device for Measuring Volumes.—Prof. Theodore Richards, says *Knowledge*, has employed a method of electrical contacts for measuring volumes very accurately. As the mercury is lowered so it can be set to just make or break an electrical contact consisting of a fine platinum point. He has used the method to determine differences in the compressibilities of liquids.

Sound Waves Produced by the Oscillatory Discharge.—The oscillating spark discharge produces sound waves which are not directly recognisable by the ear, owing to their high frequency Their presence has, however, been demonstrated by Messrs Campbell and Dye, as described in the *Electrician* by a modification of the well-known Kundt's dust tube, A glass tube closed at one end is placed in front of the spark gap, in such manner that the sound waves are reflected at the bottom of the tube, forming loops and nodes. In order to ascertain the position of these loops and nodes, a small amount of lycopodium powder is sprinkled in the tube, when it collects in small heaps at the nodes In this way the experimenters ascertained the existence of sound vibrations of a frequency lying between 140,000 and 800,000 periods per second.

A Wireless Automobile.—A number of cadets from a military academy of the Northwest is now making a tour of about three thousand miles through the East and back to Chicago in four automobiles, whose engines drive the generators for the electricity of the wireless apparatus with which each machine is equipped and the machines are operated about thirty or forty miles apart, communication being maintained by means of the wireless Each machine is provided with an extension mast, while balloons, also forming part of the equipment of each machine, can be utilised for carrying the antenna wires to any desired height The expedition anticipates visiting Washington, Annapolis, New York, West Point and other points of interest throughout the East.

Calibrating Tubes by Electric Resistance Measurement.—The measurement of resistance of a mercury column has been employed by T R. Merton to calibrate capillary tubes, always a troublesome proceeding when done by measuring the change in length of a pellet of mercury. The English periodical *Knowledge* describes Mr. Merton's method as follows: The ends of the capillary tube communicate with two mercury cups which are connected to one arm of a Wheatstone's bridge. The mean radius r is given by $r^4 = \frac{1+2dr}{\kappa s f}$ where l is the length of the capillary, f the found resistance and d a correction for the stream lines at the ends of the capillary, κ the specific conductivity of mercury It has occurred to the writer that measurements of volume in gas burettes might be made by inserting an iron resistance wire down the burette inside so that the mercury uncovers more or less of the wire as it is raised or lowered, the change in resistance of the wire being accurately measured.

Handling Iron Ore with Electric Magnets.—The *Electrical World* states that at Moose Mountain Mine in Ontario, Canada, high-grade magnetic iron ore is picked from the ground and loaded into cars by electro-magnets. The ferrous material found on the side of a hill is loosened and broken down by blasting, and rolls to the foot of the hill, where an electro-magnet, mounted on a crane, picks it up and loads it into mine cars, at the same time making a rough separation, since rock and non-magnetic material are left behind. The electro-magnet can handle 1,200 pounds of pig-iron at a load, but the magnetic quality of the unrefined ore is such that 800 pounds can be picked up easily. This is the average of a number of loads the individual lift sometimes being several hundred pounds greater. A steam shovel was formerly used for loading the ore, but the density and hardness of the magnetic destroyed the buckets rapidly. The electro-magnets also save handling a quantity of stone, and thus relieve the crushing and magnetic separating plant, where the material is concentrated before being shipped.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are sharp, the articles short, and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately and in simple terms, the world's progress in scientific knowledge and industrial achievement. It seeks to present this information in a form so readable and readily understood, as to set forth and emphasize the inherent charm and fascination of science.

The New Aerotechnical Institute in Paris

ONE of the most notable events of the year, both to aeronauts and to the scientific world in general, is the establishment of the great laboratory to be known as "L'Institut Aerotechnique de l'Universite de Paris."

The donor is M. Henri Deutsch de la Meurthe, long known as a munificent patron of those daring spirits who are seeking the conquest of the air. The opening exercises took place on the sixth of July before a distinguished assemblage, the inaugural address being delivered by Prof. Appell, member of the Academy and Dean of the Faculty of Sciences.

The institute consists of an immense laboratory for the study of practical problems in aeronautics by the aid of the most advanced science and with an equipment as perfect as possible. An important feature is a track 4,593 feet long, on which specially constructed cars run, giving opportunity for the study of the operation of planes, propellers, and other parts of the machines when moving through the air at high speed.

There are associated laboratories of Physics, Chemistry, and Mechanics for the investigation of the materials used, with reference to such questions as their purity, durability, elasticity, strength, and resistance.

The services rendered by this remarkable institution will be twofold. In the first place there will be a permanent staff of investigators making methodical researches in the endeavor to ascertain the fundamental data necessary to aeronautical achievement. Secondly, the establishment will be open to inventors and builders of aircraft who wish to test their apparatus, and to makers desirous of trying out new ideas. Furthermore, all its resources will be put expressly at the disposition of officers and engineers designated by the respective Ministers of War of the Marine, and of Public Works.

The plans have been conceived and executed by the well-known engineer, M. Hugon. Details of management, programs of experiment, and methods of research have been elaborated by a council composed of the founder, of officers and engineers representing the ministers concerned, of builders and practical airmen, and of competent scientists and members of the faculty, such as the professor of Experimental Mechanics and the nominee to the Chair of Aviation founded by M. Basil Zaharoff.

In a brief *resume* of the chief problems to be attacked, Prof. Appell pointed out that the motor was the very heart of all aircraft, whether dirigibles or aeroplanes, and in the case of the latter the slightest defect in this essential organ, such as imperfect action of the carburetor, or ignition or lubrication system, might precipitate a catastrophe. Hence there is special provision of a thorough equipment in the institute for the determination of the essential facts regarding motors, such as consumption of fuel, horse-power, revolutions per minute, etc.

Of almost equal importance are the propellers. Hence endeavors will be made to ascertain the characteristics upon which the propulsive power and efficiency of propellers depend, besides determining whether their action is the same when revolving in an artificial current of air as when driving a machine through the atmosphere.

"But the most important and as yet the most obscure subject of all," remarks Prof. Appell, "is Aero-dynamics itself. What are the laws of the resistance of the air? Can they be exactly determined by placing a plane in an artificial current of air as in the admirable experiments recently conducted by M. Eiffel? Or must we admit that the phenomena affecting the back of the plane differ according to whether it is placed in a current of air from a blower or whether it is driven forward in free air like the wing of an aeroplane? An experimental thesis recently presented to the faculty by the Duc de Guiche tends to confirm such a difference."

It will be an object of the institute to carefully compare such experiments as these, and the car running on a track is expected to be particularly useful in this connection. Besides a car for testing propellers there will be a second one electrically propelled, which will be used for testing full-sized aeroplanes, at a possible speed of 110 kilometers (68.3 miles) per hour. Registering apparatus will permit the measurement of the various pressures it is desirable to determine.

For experiments with smaller surfaces a special circular building, the largest ever constructed for this purpose, will be used.

These cars will be very useful to inventors who wish to test their devices. By placing the machine, or a reduced model of it, on the car, it may be seen at once whether practice confirms theory.

In the same way may be estimated without danger to the pilot the influence of the shape of the wings, of their angle of attack, of the inclination of the rudders, as well as the value of various passive resistances.

All these results will serve, as Prof. Appell points out, for the establishment of fundamental formulæ. "The general equations of the movement of the aeroplane have been given," he observes, "authoritatively by our colleague, M. Painleve (in his treatise, *On the Dynamics of the Aeroplane*), but they still contain many unknown coefficients.

"The determination of these coefficients must be made by careful experimentation. The experience of actual flight is too complex, as all the elements of the machine are operating at the same time, and it is hence impossible to study separately the effect of each of them. The method of the car, on the contrary, permits the analytic study of the individual role of each part, and the founding of the technique of the aeroplane upon a solid scientific basis."

One of the chief aims of this new research laboratory is the solving of the problem of automatic stability, which is the principal problem still remaining for the aeronautical engineer to clear up. The long track in the open air will make possible the testing of all sorts of stabilizing devices under actual conditions of flight, while similar tests on models can be made on the track within the circular building. A power plant of 200 horse-power furnishes ample electricity to drive the testing cars at high speeds.

The whole concept and execution of this great enterprise breathe a generosity and public-spirited endeavor creditable alike to the founder and to the savants associated with him. It cannot fail to be productive of results of great and permanent value in the new art of air traffic.

A New Relic of the Parthenon Gables

THE extant sculptures of the Parthenon, which the current opinion erroneously attributes to the great Pheidias, are distributed in four principal groups. Several fine horse heads of the east gable and two coupled human figures of the west gable remain *in situ* on the front and back cornices of the famous temple. The building retains, also, the twenty-eight mutilated metopes of its exterior, Doric friezes at front and back, and the sixteen very slightly injured relief slabs of its low relief Ionic frieze at the west end of the temple, where the procession of Athenian horsemen is still forming. Lord Elgin's Italian agent Lusieri spared some additional blocks of both friezes on the long north and south sides of the ruin, when he threw its cornices down to free and extract the sections which he conveyed to London through the vicissitudes of the Napoleonic blockades. It will be remembered that Lord Elgin himself was held prisoner in France for a season. But only one of his consignments of Athenian marbles was captured by a French frigate. The Scotch earl's generous rival, the Marquis de Choiseul, purchased and returned this to its British owner without charge. Part of the broken but superb torso of Poseidon, another torso supposed to be Prometheus, and the semi-figure of the moon goddess Selene driving her steeds into the brine are among the Parthenon marbles preserved in the Akropolis Museum. Another is the splendid frieze block with the sacrificial cows, which Count de Laborde excavated at the foot of the temple in 1840. A more recent excavation at Athens resulted in the recovery of the head of Hebe from the east frieze. Athens has never yet forgiven Lord Elgin's capture of the major part of its Periklean inheritance in carven stone. The Elgin collection became the property of the British nation for 86,000 pounds sterling in 1816, and has been the British Museum's most priceless of art treasures ever since.

The Louvre Museum, across the Channel, has the single slab of marching Athenian maidens which Choiseul secured. It is likely enough that France and not England would have got the whole treasure if Nelson had lost the battle of the Nile in 1799. The present Duc de Laborde has a fine female head from one of the Parthenon pediments at his Paris *hotel*. This relic reached France by way of Venice. Some scholars believe it to be a remnant of the Victory who drove Athena's car in the west gable.

Besides the Choiseul slab, the Louvre owns the detached head of a Lapith from one of the centaur metopes at London. An American specialist, Dr. Charles Waldstein, first fitted the two together.

So much for the Parthenon sculptures at Athens, London and Paris.

Very few other fragments of the world's most renowned group of decorative sculptures have been located. The celebrated horseman of the Vatican was once classed as one. But it was only the tombstone of some Athenian roughrider. Palermo has a pretty fragment of the eastward Ionic frieze, the Duke of Modena at Vienna has another of the south frieze; a third frieze fragment was recovered from a garden rockery in the north of England a few years back. Carlsruhe and Copenhagen have pieces of Parthenon metope slabs from the Doric frieze of the temple.

Dr. Jan Six, the son of the Amsterdam medalist, and a descendant of Rembrandt's familiar Burgomaster Six, has the merit, and the rare good fortune, of locating a very important, new fragment of the Parthenonian pediment groups, in the Royal Museum of Stockholm. A female head which he has just published in *The Journal of Hellenic Studies* has hitherto borne the perfectly arbitrary name of "Dejanira." The Stockholm marble has the same characteristic blocked modeling as the badly weathered head of the London "Theseus," and that statue is the only complete pedimental figure with a head on its shoulders. The new marble agrees, in this resemblance, with the Duc de Laborde's female head. This *air de famille* is, indeed, the clinching argument for the attribution of both the detached heads to the studio of the Parthenon sculptors. For of heads and statues chiseled over life size in Pentelic marble there are many. It is the eye that must decide. Kalkmann and other classical archæologists have enriched the machinery of their favorite science with tables of comparative dimensions which are a lame substitute, at best, for the immediate perceptions of that sensitive organ. We suppress the dry figures in the present case.

Persons familiar with Anna Akerhjelm's letter to her brother Sam, containing a contemporary account of the explosion and wreck of the Parthenon by a Venetian shell, in 1687, will find the Dutch critic's lucky location of a trophy of the fall of Athens in Sweden no more surprising than Weber's purchase of a similar one at Venice. Anna was a Swedish companion of Countess Konigsmark on board of Francesco Morosini's squadron. Count Konigsmark himself commanded a force of Hessian mercenaries under Morosini. One of his Germans pointed the fatal mortar which compelled the Turkish garrison's surrender of the citadel on September 28th of that year. A deserter had brought Konigsmark the information that the great temple was the enemy's chief casemate and powder magazine. Three hundred souls lost their lives in the historic explosion. The number included the harem of the Turkish commandant.

One may indulge the fancy that Sam Akerhjelm's sister carried the Stockholm head to Sweden, just as some other follower of Morosini must have taken the Weber-Laborde head to Venice. As a matter of record, the broken Greek head was in a collection made at the royal Swedish castle of Drottningholm by Frederick the Great's sister Queen Louisa Ulrica of Sweden, before her accession in 1749.

William Napier Shaw, F.R.S.

The Head of the Official Meteorological World

By C. Fitzhugh Talman

WHEN the lamented Mascart, shortly before his death in 1907, relinquished the presidency of the International Meteorological Committee—an association comprising the directors of the principal national weather services of the world—the choice of his successor entailed no delay or discussion. The committee was singularly fortunate in having among its members a man ideally fitted to occupy the by no means easy position of head of official international meteorology. Others had contributed more conspicuously than Dr. Shaw to the advancement of the world's knowledge of the atmosphere; but no one even approached him in those personal qualities that stand for successful leadership.

Dr. William Napier Shaw, president of the International Meteorological Committee and director of the British Meteorological Office, is a man whose personality compels attention. Physically, he is above the average in build and stature. Anyone who is prone to notice canine affinities in the human species would unhesitatingly class him among the mastiffs. Temperamentally, he is placid and self-contained, suave and tactful, under all the harassing circumstances that beset him as an administrator, national and international. Intellectually, he is the kind of man in whom we like to see the realization of the ideals of the English universities. His *métier* happens to be physical science; but this fact does not warp his appreciation of the humanities. In his public addresses he is prone to quote poetry. The quotations are always felicitous, and fit in quite naturally with the speaker's graceful prose, which has itself a poetical undercurrent.

Born at Birmingham in 1854, he was educated first at King Edward's School, in his native town, and then at Emmanuel College, Cambridge. His studies in physics were rounded out at the University of Berlin, under Helmholtz, whence he returned to Cambridge as fellow of Emmanuel, becoming later university lecturer in experimental physics, and then assistant director of the Cavendish Laboratory.

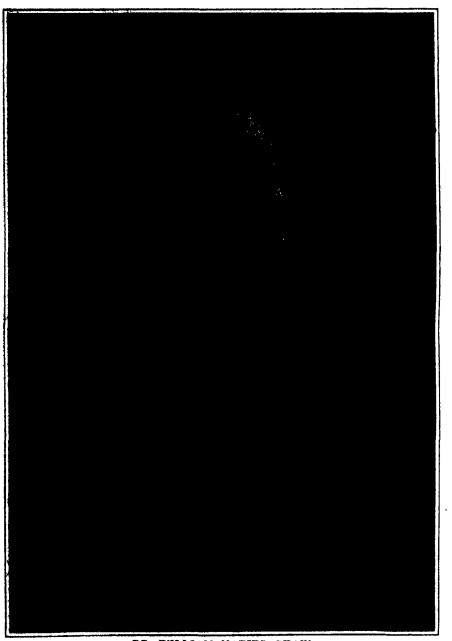
In 1885, after the introduction of "New Statutes for the University and Colleges," he married Sarah, second daughter of Dr. T. Harland, of Salford, herself attached to the teaching staff of the university, as lecturer in mathematics at Newnham. Mrs. Shaw has kept up her interest in educational matters, and is an active leader in the educational section of the British Association. She is also an ardent amateur photographer, and we are indebted to her skill in this direction for the portrait of her husband that accompanies this article.

From the beginning of his academic career, Shaw displayed an interest in certain applications of physics to meteorology, and he carried out special investigations for the Meteorological Council of the Royal Society long before he dreamed that he should one day be called to the directorship of the Meteorological Office. The first course he gave as lecturer on natural science at Cambridge was on meteorological instruments, in 1897. Fortunately, however, for his subsequent career as a meteorologist, he was at the same time laying the secure foundations of a general knowledge of physics and mathematics—the necessary propedeutics of all serious work in meteorology. A glance at the list of his contributions to scientific literature during his residence at Cambridge reveals an extraordinarily wide range of interests; electrolysis, ventilation, acoustics, pyrometry, thermodynamic problems, were a few of the subjects that he attacked with especial zeal, and to which, in each case, he added something of his own. As early as 1895 he published, conjointly with Glazebrook (now director of the National Physical Laboratory), a textbook of practical physics, which has passed through several editions.

When in 1891 he was elected a fellow of the Royal Society he held a commanding position among physicists, and his genius as an educator was conceded to have placed the teaching of physics at Cambridge upon a more dignified footing than had ever before been granted to it—but he was hardly yet accounted a meteorologist. In 1897 he succeeded Stone, the Oxford astronomer, as a member of the Meteorological Council of the Royal Society—which was, in those days, the governing body of the Meteorological Office. Not until 1900, however, did he definitely embark upon a meteorological career. In that year R. H. Scott retired from the position of administrator of the Meteorological Office (as secretary of the council), and Shaw was called from Cambridge to succeed him.

From the moment that he took up his new work in what, in a recent tribute to a deceased colleague, he has called "the unpretentious room over a piano shop in Victoria Street which for more than forty years has been the chief center of meteorological work in this country," the Meteorological Office awoke to new life. Official meteorology is not generously treated by the British government. It is supported by an annual Parliamentary grant which, together with miscellaneous revenues from other sources, amounts to less than $100,000; i. e., about one-sixteenth as much as Congress appropriates annually for the United States Weather Bureau. How, with the meager means at his disposal, the director of the Meteorological Office is able to keep up even the routine of a great national weather service is a mystery to his cisatlantic confreres. This routine work includes among other things the preparation and publication of daily, weekly, monthly and annual reports, containing the results of observations at a few large observatories and a great number of small stations. In response to the frequently expressed desire of the International Committee for the prompt publication of data, Dr. Shaw has gradually brought up the arrears of these reports, which now appear so punctually that they set the pace for all publications of similar character throughout the world. Formerly one had to wait three or four years for the *de rigueur* returns of the English meteorological observatories, now one gets them in as many months.

The compilation of these returns, the daily weather forecasts, and the superintendence of the instrumental equipment, along with incidental clerical duties, might well be expected to absorb all the energies of the little staff of meteorologists and clerks, formerly housed in the cramped quarters "over a piano shop" for which Dr. Shaw's epithet "unpretentious" was somewhat unduly charitable—but, since last year, more happily installed in new and relatively spacious premises in South Kensington. Such, however, is far indeed from being the case. At brief intervals the office publishes memoirs on special topics, ranging over a wide field, and so pregnant with timely interest as to give outsiders the impression of being the fruit of ample leisure rather than of odd moments snatched from the "trivial round."



If it be asked what all this has to do with the subject of our sketch, the answer is that all the publications of the office bear, at least the unmistakable marks of his directive genius, and not a few of them have come chiefly from his own pen. In an address before the British Association a few years ago he expressed his views as to the relation of routine to extra-routine duties at the office in the following words:

"There is a tendency among some of my meteorological friends to consider that a meteorological establishment can be regarded as alive, and even in good health, if it keeps up its regular output of observations in proper order and up to date. That is a view that I should like to see changed. To me, I confess, the speculation which may be dignified by the name of meteorological research is the part of the office work which makes the drudgery of routine tolerable. For my part I should like every worker in the office, no matter how humble his position may be somehow or other to have the opportunity of realizing that he is taking part in the unraveling of the mysteries of the weather, and I do not think that any establishment, or section of an establishment, that depends upon science can be regarded as really alive unless it feels itself in active touch with that speculation which results in the advancement of knowledge."

Since his election to the presidency of the International Meteorological Committee in 1907 Dr. Shaw has displayed, on a larger scale, the same genius for organizing and directing scientific work that distinguished him when, in his earlier years, he built up the department of physics at Cambridge, and that he later brought to bear upon the task of reorganizing and revivifying the Meteorological Office. Meteorology stood in need of just such a leader. He is not, as the typical Englishman is reputed to be, unduly wedded to the past. On the contrary he is sometimes criticised for being in advance of his times. He has, for example, led the movement that aims to reform the units of measurement employed in meteorology and stands ready to throw overboard the whole cumbersome system of inches and feet and Fahrenheit degrees, he has, in fact, already done so in the upper air work of the office.

A few evidences only can be quoted in this brief sketch of the advanced position that he has come to occupy in the general campaign of meteorological research. There is urgent need of gathering in the scattered results of climatological observations made in countries that have no regular weather services. In recognition of this need Dr. Shaw has set the example by undertaking to publish all such data obtainable in the smaller British colonies, and heretofore almost wholly inaccessible to the scientific public.

(Continued on page 176.)

DR. WILLIAM NAPIER SHAW

President of the International Meteorological Committee.

Integral Photography

A New Discovery by Professor Lippmann

By the French Correspondent of the Scientific American

PROF LIPPMANN of Paris is working on a very remarkable new photographic method which he has termed "integral photography" The nature of this is best explained by reference to the accompanying diagram It should be remarked in the first place that the process is designed to work without a camera. The sensitized plate is coated with a large number of very small globules of glass or other transparent material In use each of these acts as a miniature eye, with a sensitive plate for its retina The globules are very small, less than one hundredth of an inch in diameter In front each has a little blob which acts as the lens of the miniature eye Suppose an object to be situated at *M M'*, as indicated in the diagram Consider any globule Rays from the points *M M'* will pass through the minute lens, and an image will be formed at the back of the globule upon the sensitized plate at *M M'* Thus each globule will contain a minute picture of the objects placed in front of the plate This picture is brought out by developing the plate and fixing it in the usual way This of course yields a negative, which must be reversed by the use of a suitable reversing bath The result is a transparency, in which all the minute pictures in the individual globules are combined into one image of the original object To view it, a good light is placed behind the plate, so as to send light through all the globules Suppose the eye viewing the transparency to be placed at *O*, the point which when the picture was taken, lay on a line joining one globule with the point *M* of the object The process which now occurs will be the opposite of what happened when the picture was taken In other words the eye will receive from the globule a view of the image *m* of the point *M* Other globules will send images of the point *M'*, etc, at the same time, so that the eye will see the different portions of the image coming from all the different globules In this way a complete image of the object originally presented to the plate is seen If the eye is placed at some other point *O'*, or if *O'* represents the position of the other eye, the object will also be seen, but the light received at the eye will come from somewhat different portions of the globules, and the appearance presented will differ accordingly from that seen at *O* The difference is of precisely the same kind as that which distinguished the appearance of the same object when seen from two different points In other words, when passing from *O* to *O'*, the observer will receive the same impression, in looking at the transparency, that he would if he were to move in this way while looking at the original object For example, in one position a certain object might be hidden behind a tree, in the second position this object might become visible Again, if *O* and *O'* should represent the positions of the two eyes, each will receive a slightly different impression, with the result that a stereoscopic effect is secured This is explained by the fact that certain portions of the landscape appear in certain of the globules, but not in others The image which the eye sees is made up of points coming from different globules, and as the eye moves, and different pairs of each globule are viewed, the contribution which each sends to the eye is changed in accordance with the direction in which the eye is looking at the globule

After working out this remarkable principle, Prof. Lippmann presented it before the French Academy of Sciences and other scientific societies, where it awakened great interest. The realization of the process presents considerable technical difficulties Owing to their small size, it was out of the question to shape each one of the globules separately Prof Lippmann tried using minute glass beads, such as are found in commerce and used for covering ornamental surfaces, such as picture post cards He found, however, that these were too irregular in shape and size Another idea which suggested itself was to stamp out a transparent sheet of collodion and gelatine, giving the surface the requisite shape But the dies required were found to be too difficult to make in the laboratory, so that Prof Lippmann has been forced to abandon his attempts in this direction for the time being The fact is that the working out of a process of this kind is a technical

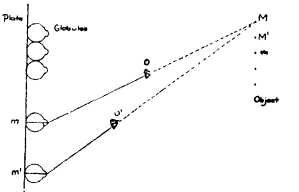


Diagram to illustrate the principle of Lippmann's integral photography.

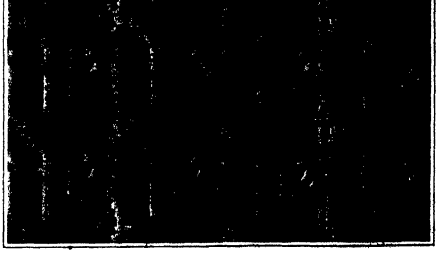
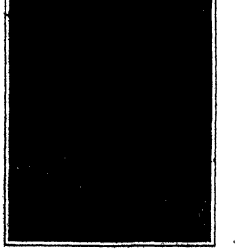
rather than a scientific problem. There is a good field here for inventors to exercise their ingenuity, for if a Lippmann photographic plate could be made it would be of great value, inasmuch as in order to take a photograph the plate is simply exposed to a landscape or other object, without any camera at all, and the picture obtained possesses the remarkable properties explained above



In the meantime Prof Lippmann has been making some interesting experiments with an apparatus which is intended to show some practical results of the principle expounded, and without use of such minute globules he has succeeded in producing some very striking effects A number of ordinary lenses (even spectacle lenses may be used) are cut into square shape, so that they can be fitted together into a continuous surface A number of such lenses are put in the front wall of a camera, as shown in our illustration The more lenses are used, the better is the result obtained, but twelve is found to be a sufficient number These lenses correspond to the globules spoken of above, each image being formed on a separate portion of the photographic plate at the back of the camera Each lens makes a picture on the plate, the portions of the plate illuminated by the several lenses being kept separate by an arrangement of black cardboard cells or partitions. One of our views represents the front of the camera with a set of twelve lenses, while the rear view shows the cells in the plate-holder This latter carries a large plate of such size as to receive all the twelve pictures, and is placed in the camera as usual. The plate-holder, however, is made with a slide in the back as well as in the front, for a purpose which will appear presently After the picture is taken, the negative is developed as usual, and is reversed either by means of a reversing bath, or by copying it, so that a transparent positive is obtained. The twelve pictures are not quite alike, for each lens forms its image from a somewhat different point of view The transparency is put back in the holder, both slides of which are now opened, while light is sent through from behind The observer looks in through the lenses with both eyes, when he sees a single view in relief of the object photographed. On moving the head from side to side, or up and down, the same effect is observed as would be under similar circumstances when looking at the real object, that is to say, objects which cover one another when looked at from one point, are seen to separate when viewed from another Even with this simple apparatus the effect is very pleasing.

Proposed Aeronautic Map



AT a recent meeting of the Academie des Sciences, M Lallemand, chief of the French Government Survey Department, presented the project which the Aeronautic Commission intends to carry out establishing an aeronautic map The proposed map is of 1:200,000 size, and is drawn up after a provisory model made by the Aero Club Each plate of the aeronautic map will be a sheet taking in one degree in latitude and longitude and there will be twenty-four such sheets included in one sheet of the world's map. This latter sheet occupies 6 degrees longitude by 4 degrees latitude. The longitude will be counted from 0 degrees to 360 degrees toward the east starting from the meridian lying exactly opposite to Greenwich, and the latitudes, or rather the distances from the South Pole, will be numbered from 0 to 180 degrees toward the north. Each sheet will carry a number which designates it On the other hand, on the ground or the roof of a building will be traced a large square, and the position of that particular locality on the map is shown by a large circle or disk To the left will be placed a large number showing the units of the latitude and to the right the figure for the longitude, but using only the unit figures in each case, as an error of 10 degrees, or from 600 to 700 miles, could hardly be made by a pilot as to his position, so that such figures will be enough to guide him. Thus he finds what leaf of the map he is to use for this locality. In order to make a trial of the new plan, it was decided that three specimen sheets of the map should be made by the Aero Club, and these will be put in the hands of the army pilots during the next annual maneuvers

Prof Lippmann's camera, showing the front with its twelve lenses

View in Prof. Lippmann's laboratory. A twelve-fold image formed by as many lenses.

The rear of the camera, showing the cells and plate-holder.

APPARATUS AND RESULTS OF THE NEW LIPPMANN METHOD OF PHOTOGRAPHY

Water in Motion

Some Examples of the Tremendous Energy of Waves and Floods

MEASUREMENTS of the size of waves have now been made systematically for many years, but they relate chiefly to the waves of the open sea, where the depth of the water is so great that the friction of the sea bottom exercises no modifying effect

A few months ago the North German Lloyd liner "Brandenburg" came into New York harbor with her crow's nest, 50 feet above the water-line, stove in, and bearing many other marks of the damage wrought by a monster wave that broke over her bows about 1,000 miles east of Sandy Hook The officers estimated the height of the wave at 65 feet This height is exceptional, but not unprecedented, for it must be remembered that the breaking of a wave against an obstacle throws the water to a far greater height than the unbroken wave could attain.

Unbroken waves due to the wind may, in extreme cases, reach a height from trough to crest of 40 to 50 feet Much higher waves occasionally occur as a result of earthquakes or seaquakes. "Solitary" waves of this character have sometimes been encountered in otherwise tranquil weather, taking vessels by surprise and not infrequently sending them to the bottom

According to Vaughan Cornish, who has probably devoted more attention to this subject than any other contemporary man of science, the average height of the waves encountered in a severe storm at sea is 20 feet, but the ordinary maximum height of the waves in the same storm will attain 30 feet In a storm of very exceptional violence the average height may reach 30 feet, and the maximum height 45 feet. This is regarded as about the limit of the height of waves due to wind only Cornish finds that in the open sea the height of a wave in feet is about one-half the velocity of the wind in miles per hour The following table, computed by W. H. Wheeler from a great number of observations, shows the relation of the wind to the dimensions and speed of ocean waves.

Wind.			Waves			
Speed.*		Force, Pounds per Sq. Ft.	Height in Feet	Length in Feet	Speed.	
Feet per Second.	Statute Miles per Hour				Feet per Second	Nautical Miles per Hour
2	1½	0 02	0 08	1 5 4	2 32	1 4
6	4	0 08	1 98	52 2	9 56	5 6
18	9	0 36	4 99	119 1	15 08	9 0
30	14	1	9 69	174 0	23 91	13 9
37	17	1 60	8 61	254 9	31 32	18 5
80	90	9	9 00	261 0	34 80	20 8
95	94	8	11 95	304 5	40 40	24 0
44	30	5	14 58	382 8	51 00	30 6
59	40	8	19 47	513 3	68 44	41 0

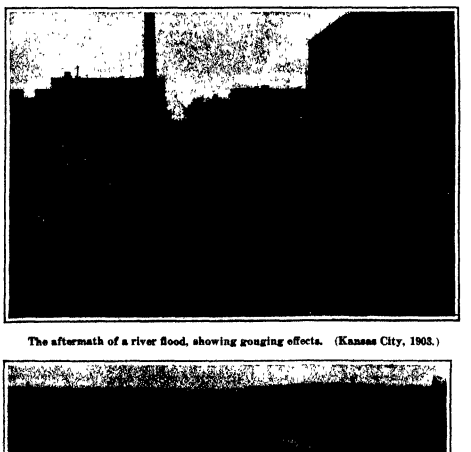
118	80	36	The proportions of these waves are so curious that averages cannot be given			
147	100	50				

So much for waves on the high seas These waves, though they may race along at the speed of an express train, do not carry the surface water far with them, each particle of water describes a local circular orbit during the transit of the wave, so that what advances is rather the form than the substance

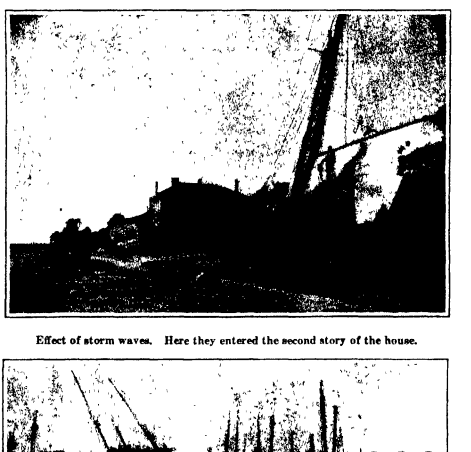
The case is quite different when waves break upon a shore, where the shoaling water produces "waves of translation" These waves are relatively short and steep, and break when they enter water the depth of which is equal to, or a little exceeds, their height from trough to crest They approach the shore in a direction nearly at right angles to the general shore line, whatever the direction of the wind This is explained by the fact that, if the wave is at first directed at an acute angle to the shore, when it reaches shallow water the side of the wave nearest the shore is first retarded, so that the wave tends to swing around until it faces the shore

In planning harbor construction and the protection of coasts it is customary to consider the amount of exposure to which the coast is subject, i e, the extent of open sea in a straight line at right angles to the shore This is called technically the "fetch" The relation of the fetch to the possible height of the waves was announced by Stevenson in 1852 According to his formula the height of waves in a gale, in feet, is one and one-half times the square root of the length of the fetch in nautical miles



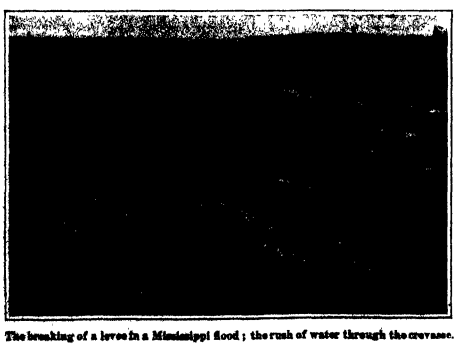
The force of a great wave breaking against a sea wall or other construction is so terrific as to tax the strength of the best planned work of the engineer A marine dynamometer for measuring the force of impact of such waves was devised by Stevenson over half a century ago, and modifications of this instrument have since been introduced by several investigators According to Stevenson, the maximum force of an Atlantic wave is three tons per square foot French engineers find that the force of the waves on the breakwater at Cherbourg may attain three and a half tons per square foot.

Some interesting examples of the height to which breaking waves may be thrown, and the work they may do in moving heavy objects, are given by Wheeler in his 'Practical Manual of Tides and Waves'



Stevenson records a case in which water was thrown to a height of 106 feet at the Bell Rock Light At the Alderney breakwater it is said that water has been thrown upward 200 feet At Peterhead, where the "fetch" is 300 miles, waves of 30 feet in height and from 500 to 600 feet in length have been recorded, the water has struck the breakwater with such force as to be thrown upward 120 feet, and blocks of concrete weighing 40 tons have been displaced at levels of 17 to 36 feet below low water

At Wick two stones, weighing eight and ten tons each, were thrown over the parapet of the breakwater, the top of which was 21 feet above high water, while blocks of concrete weighing respectively 1,350 and



* These particular intervals of wind speed were chosen as representing the successive steps of the "Beaufort scale," according to the equivalents formerly assumed for this scale As the latter are now known to have been much too great, we have omitted the Beaufort numbers from Wheeler's table.

The aftermath of a river flood, showing gouging effects. (Kansas City, 1903.)

Effect of storm waves. Here they entered the second story of the house.

The breaking of a levee in a Mississippi flood; the rush of water through the crevasse.

Havoc wrought by storm waves in a Gulf hurricane.

SOME EXAMPLES OF THE TREMENDOUS ENERGY OF WAVES AND FLOODS

2,500 tons were displaced, though there is some doubt whether the latter movement was due entirely to wave action

At the Bishop Rock lighthouse, which is exposed to the full force of the Atlantic waves, an iron column weighing over three tons was thrown up 20 feet and landed on top of a rock.

At the harbor works of Bilbon, in 1894, a solid block of the breakwater weighing 1,700 tons was overturned from its place and dropped into the water

At Ymuiden breakwater a block of concrete weighing twenty tons, placed outside the harbor walls, was lifted by a wave to a height of 12 feet vertically and landed on top of the pier, which was 5 feet above high water.

The above cases illustrate the sheer force of the individual wave as an engine of destruction, but the imagination of mankind is more impressed by the widespread effects wrought by the great storm waves that sometimes inundate low-lying coasts These waves are often miscalled "tidal waves," the only justification of the latter name being the fact that their effects are most pronounced when the wave propagated outward from a storm area happens to coincide with the occurrence of flood tide on the coast affected

The precise mode of origin of the storm wave has been the subject of much discussion, and even now is not fully understood Such waves attend every severe cyclonic storm at sea, and as they travel much faster than the storm (i e, the storm as a whole, not the wind revolving about the storm center) they often occur on a coast when the weather is otherwise serene, and thus serve as a valuable prognostic of the storm's approach, in case the coast happens to lie in the storm track.

It is well known that the barometric pressure is much lower at the center than at the periphery of a storm—the difference sometimes amounting to two inches or more—and this difference of pressure must disturb the equilibrium of the water, causing it to become heaped up at the storm center This bulging of the water would amount, theoretically, to about one foot for each inch of barometric depression However, although this process doubtless contributes to the production of the wave, the violent winds at the vortex of the storm are probably a much more important factor

The mechanism of storm waves was studied by a board appointed by the Chief of the United States Weather Bureau for this purpose in 1901; and the reader is referred to the report of the board, published in the *Monthly Weather Review* of October, 1901, for further information on the subject

We are concerned here chiefly with the effects of storm waves (which the newspapers and the public call "tidal waves," but persistently, and with as much reason, as they call tornadoes "cyclones") These are most severe when the wave moves toward a low-lying coastal region, having a converging shore-line, this convergence producing the same effect as seen in a tidal "bore"

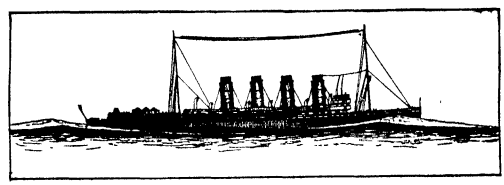
The most disastrous storm waves have occurred along the coast of the Bay of Bengal, on the extensive flats lying about the mouths of the Hugli, the Meghna, etc The storm wave of October 7th, 1737, is said to have risen 40 feet in the Hugli, sweeping away 300,000 souls In May, 1787, at Coringa, near the mouth of the Godavery, such a wave is said to have taken toll of 20,000 lives The Calcutta cyclone of October 5th, 1864, caused the inundation of the flats on both sides of the Hugli estuary, with a loss of about 48,000 human lives, and the destruction of 100,000 head of cattle The greatest disaster of recent times in this much-afflicted region was the Backergunge hurricane of the night of October 31st-November 1st, 1876, which cost the lives of over 100,000 persons In this storm the water rose from 30 to 40 feet in less than half an hour

The islands of the Pacific are also subject to visitations of this character on a huge scale, in connection with tropical hurricanes The latest of these was the storm of March, 1910, which was especially remarkable for the vast area that it covered, its track extending some 2,500 miles, from Fiji to New Caledonia, Norfolk Island and the North Island of New Zealand Statistics of the loss of life and property in this storm are not yet available

Our own seaboard has repeatedly suffered from the effects of storm waves. In the Galveston hurricane of September, 1900, a series of waves invaded the city; 6,000 lives were lost, and the destruction of property amounted to $30,000,000. The damage was due to wind as well as water, but chiefly to the latter.

It remains to say a word concerning quite another kind of wave, viz., that which moves down a river in flood, often causing widespread inundations of the adjoining shores

The total volume of water discharged by a great river is so enormous that it is commonly expressed in units of a million cubic yards. The normal annual discharge of the Mississippi system is 785,190 of these units The occurrence of a flood depends upon many factors, which fortunately rarely combine their maximum effects at a given moment. Thus the maximum *possible* discharge of the lower Mississippi is about 3,000,000 cubic feet per second, which is about one-third greater than has ever occurred, so far as known.



The most destructive river floods of which history furnishes any record are those that have occurred in China, especially those of the Hwang-Ho—"China's Sorrow" We hear of occasional changes in the course of the Mississippi, whereby a property-holder is presented with, or robbed of, a few acres of alluvial land over night, or a cut-off shifts a few square miles of land from one bank to the other; but what shall we say of a river that has bodily abandoned hundreds of miles of its channel no less than nine times, thus changing the position of its mouth to the extent of five degrees of latitude? The havoc wrought by these migrations of the Hwang-Ho—to say nothing of the floods that have not involved a general shifting of the channel—staggers imagination It is most conveniently stated in terms of human lives swept away; and we are told that during the fifteen years beginning with 1851 (including the last great change in the course of the river) between forty and fifty million human beings fell a prey to the fury of the waters.

The floods of the Seine, of recent memory, as well as all other similar disasters of the western world, sink into insignificance in comparison with this record.

What of the means of ameliorating the regimen of our rivers—diminishing their liability to flood? Forestation used to be considered the panacea, but to-day our judgment is suspended on this question The doctors disagree

River engineering has worked wonders If the destructive flood comes in spite of the engineers, then we can only look to the flood forecaster to give us timely warning—and stand from under

River stage prediction has reached—above all in America—a degree of accuracy that nearly reconciles us to the floods in consideration of the pride we feel in this particular branch of scientific achievement This, however, is subject matter for another story.

White wave line—wind 67 miles per hour; height of wave 31.35 feet; length of wave 826.5 feet
Black wave line—wind 30 miles per hour; height of wave 14.55 feet; length of wave 382.8 feet.

No Two Finger Prints Alike

SINCE the time when the late Sir Francis Galton proposed the use of "finger-prints" as means for identifying criminals, soldiers, and people generally, there has been great hesitation on the part of many people to accept the absolute individuality of the markings on the finger tips as certain To most of us it is very hard to conceive that there cannot be two fingers that are exactly alike When the police try to fix the guilt for a crime by showing the identity of the finger-print of the accused with that left on a window or a weapon, for example, many people consider the evidence as far from conclusive A recent murder case in New York city involved finger-prints as evidence of identity, and the attorneys of the defendant appealed the case on the ground that the evidence left room for "reasonable doubt"

A communication to the French Academy of Sciences by M V Balthazard is of interest in this connection This student finds that if any finger-print be divided into a hundred squares, each square will contain some distinctive mark, rarely two marks and only in very exceptional cases three or none These marks are either the branchings of the ridges that you can see on the tip of your finger, or terminations of ridges. Two finger-prints differ from each other either in the arrangement of the marks in the different squares, or in the character of the marks in a particular square. The total number of combinations of the two kinds of marks in the hundred squares is the one-hundredth power of 4 (4^{100}). This is a number that no one can possibly imagine; it is equal approximately to a number that would be represented by the figure 1 followed by sixty zeros. This means that there are possible just so many different kinds of prints, and that no particular combination will occur more frequently than others. The chances, therefore, of any particular combination of marks occurring, may be represented by a fraction with one as the numerator and a denominator represented by 1 followed by the sixty zeros—a very tiny fraction of a chance indeed.

Now in order to compare this very slim chance with human chances generally, we must consider the population of the whole world. At the present time this is estimated to be, in round numbers, 1,500,000,000 There are about three generations in a century, or say about five thousand million different human beings As each of these has, on the average, not more than ten fingers, that makes a possibility of about 50,000 million different finger prints in a century. In order to have enough human beings to furnish the fingers necessary for realizing all the possible combinations of marks, we should need a number of years represented by the figure 2 followed by forty-eight zeros. The chances for finding two finger-prints exactly alike would be about once in that length of time.

This period is of course inconceivable, and from a practical human point of view it is as long as "eternity" This length of time is vastly greater than the total length of the period since there was any kind of life upon the earth at all; it is even much longer than the length of time that astronomers calculate as necessary for the complete freezing of the sun.

But if it would take that long, approximately, before two human finger-prints appeared that were exactly alike, one may still ask how near alike may two finger prints be. Or to put the question in its practical form In how many points must two finger-prints agree to make sure of identity? Dr Balthazard shows on purely mathematical grounds that when two finger prints agree in 17 of the 100 squares, it is practically certain that they were made by the same finger His reasoning is as follows

If we look for a single coincidence, we may find it on examining four fingers To find two finger-prints that have two coincidences, we must examine at least sixteen fingers. To find three coincidences between two finger-prints, we must examine at least sixty-four prints, etc. These numbers, it will be noticed, represent the *powers* of 4 corresponding to the number of coincidences sought Thus, $4^1 = 4$; $4^2 = 16$; $4^3 = 64$; $4^4 = 256$, etc. The probability or "chance" of any number of coincidences occurring is 1 divided by 4 raised to the power of the number of coincidences In this way we must find the number of coincidences whose probability is as 1 divided by the total number of fingers on the earth at any one time This number is slightly less than seventeen, for the seventeenth power of four (4^{17}) is 17,179,869,184. (The total population being taken at fifteen hundred millions, this number is multiplied by ten—the number of fingers for each person—giving us 15,000,000,000 fingers at any one time.)

In actual practice it may not be necessary to find as many as seventeen coincidences to make sure of identity If the two finger-prints that are being compared are known to have been made by Europeans, or by Americans, or by inhabitants of a certain district, the number of coincidences necessary to establish identity is much fewer. Bertillon found two finger-prints made by different men, having as many as thirty coincidences This would seem to be at variance with the law of probability; but on examination it appeared that the two men were twin brothers.

However, the mathematical demonstrations may not be quite convincing to many persons. The doctrine of probability may be acceptable enough, but it remains to be shown whether all the combinations that are theoretically possible do actually occur in equal numbers; that is, whether there is not a tendency for certain combinations to occur more frequently than others, and whether, therefore, certain coincidences are not more likely to occur than others. Still, the numbers involved are so enormous, that for all practical purposes we may feel quite assured that what is likely to happen only once in a long, long eternity is *not likely* to happen twice in a century.

Cosmic Speculation

To the Editor of the SCIENTIFIC AMERICAN.

To modify if not entirely to prevent dangerous thaws, intense heat-waves, extensive droughts, and seismic disturbances, should be the primary aim of mankind in the present century.

Solar rays, striking the earth at right angles, have the effect, in one region, of suddenly dissolving and releasing huge ice-jams; in another, of overheating and evaporating vast quantities of water. This mass, in its new form, accumulates heat and electricity. If the phenomenon were to recur indefinitely, it would probably result in the total disintegration of the terrestrial mass. However, there may be noted, as counteracting the influences described: (1) the revolving motion of the earth about the sun, (2) the attraction exerted upon it by the moon, and (3) the irregular formation of its crust.

Yet the proceeding does repeat itself for days and months. When the former is the case, the phenomenon brings in its trail widespread inundations and the insufferable heat that annually numbers its victims by the thousand—particularly in this very country. And in the latter instance, when the occurrence continues for a considerable length of time, an exhaustion is produced of the general humidity as well as of the aqueous deposits left by previous rains in the soil and subsoil. These deposits ordinarily feed the internal streams and lakes whose function is refrigeration.

In reducing these cooling influences, the draining off of inner bodies of water heightens the internal heat, and with it the extent of evaporation and electricity; until the moment arrives when equilibrium is upset between the inner and outer electrical states, giving birth to a wave that precipitates commotion and disturbance.

On occasion, the phenomenon takes on more serious proportions, because of greater intensity in the sun's heat or through special circumstances existing in the interior regions. These contributory causes facilitate the action of "the mighty fluid" and combine with it to hurl outward the very bowels of the earth, to make room for the processes of deformation and disintegration.

In view of the advanced state of the sciences and the increased means of action at the disposal of man, the phenomenon should allow of easy modification. The remedy is to be sought in two directions: (1) By loud reports in the upper strata of the atmosphere, we may attract currents of air bringing cold from the regions that are far distant from the scene of overheating. (2) The natural course of events can further be modified by collecting, simultaneously with the explosions on high, the electricity stored in the atmosphere and in the bosom of the earth.

Small acts determine large effects. Deprive a huge boulder of a little stone that contributes to its equilibrium, and the mighty mass will overturn. Let a man shout, a gun give forth its report or a tiger roar, at a given place and at a given moment; immediately there will be unchained a down-pour, a tempest lasting hours.

A decade or more must elapse before we can determine the precise spot and occasion for such action. For perhaps a pair of decades our plans must hold fire, until we can reach into the depths of the earth with a receiver. Yet both ends shall certainly be attained. In the meanwhile, advantage can be taken of the art of aviation and of craters and their data to study the laws of the atmosphere and general geological chemistry.

The task set before us is not one for the individual. Rather does it confront the nations. World conventions, competitive contests for generous prizes, observatories and laboratories already in existence and yet to be created, all to be united into one association better to see and better to labor—such is the path to be followed.

New York city. R. FERRES CORDERO.

The Bridgeport Railroad Wreck

To the Editor of the SCIENTIFIC AMERICAN:

In your article entitled "An Imminent Railroad Danger" in the issue of July 22nd, you speak of the "perfection of the track and equipment of our leading railroads." I feel, however, that, as far as the Federal Express is concerned, the description "perfection of equipment" does not apply. Being interested in such matters, I have frequently noticed particularly the equipment of this train as it stood in the South Station, Boston. The train usually consists of a large Pacific type locomotive followed by a baggage car (sometimes a Pennsylvania steel car), a New Haven wooden vestibuled day-coach (not of the most modern type) and then several Pullman sleepers, some of which are, sometimes, of the all steel type built for use on the Pennsylvania Railroad. According to your opinion repeatedly expressed in your paper, such a sandwiching of a weak wooden day-coach between a heavy locomotive and heavy Pullman sleepers is about the most dangerous arrangement that could be devised. The fact that nearly all the deaths occurred in the day-coach shows the validity of your contention, which, however, is not difficult to understand in the abstract.

As for the matter of human control, it seems that it ought to be possible and not seriously inconvenient to so arrange the controlling levers in the cab that it would be necessary for the engineer to exert some little pressure on them to keep the throttle open and the brakes off. Then, if, through his unconsciousness or sudden death, the pressure were released, the train would automatically be brought to a stop.

Braintree, Mass. AUBREY D. BRIDELMAN.

Possible Size of Battleships

To the Editor of the SCIENTIFIC AMERICAN:

Apropos of the limits of size of battleships, at least for the American navy, it would seem the Panama Canal sets very certain restrictions. The locks have a length of 1,000 feet, a width of 100, and a depth of 40.

Supposing the maximum draft of a battleship to be 30 feet, its length to breadth 6 1, and its beam the maximum 100 feet, we have a limit (using the coefficient of fineness 0 600) 30,000 tons. If we extend the length and breadth to 7 1, we have with the same draft of 30 feet 36,000 tons. Suppose the draft to be enlarged to 35 feet, for the first set of proportions we have again 36,000 tons, and the second set (7 1) 42,000 tons. It is hardly possible that the length of a battleship with regard to its beam will exceed 7 1 with due regard to stability as a gun platform. Coincidently, 35 feet in all probability will be the maximum possible draft, having taken into consideration the depth of our harbors, and the possibly increased draft of a disabled warship.

As it is, with the maximum dimensions of 100 feet beam, 700 feet length, and 35 feet draft, there is no dock in the United States as far as I know that will take such a ship. Hence it appears that these are the outer limits of dimensions for our battleships, for after having constructed the canal, it would be superlative madness to neutralize it by building ships which could not use it. By increasing the coefficient of fineness, a somewhat larger tonnage might be obtained. Hence it would seem that the utter limit in size of our battleships is roughly 40,000 to 45,000 tons. From 1907 to 1911 the tonnage has jumped from 20,000 to 30,000—50 per cent. At the same rate of increase, in 1915 the limit will have been reached, and the battle of displacement will have given place to the battle of calibers.

Pittsburg, Pa. WILLIAM BERGEN CHALFANT.

Photography of the Invisible Ray

To the Editor of the SCIENTIFIC AMERICAN:

I was much interested in an article appearing in the SCIENTIFIC AMERICAN under date of June 10th upon "Photography by Invisible Rays," with photo illustrations of the theory. If you will look in a "Science Record" of 1874, published by Munn & Co., under the heading of "Photometry of Colors," you will find a brief outlining of some crude experiments I made to determine so far as possible the relative focal length of the colors of the solar spectrum, concluding that the shorter the focal length of a color, the greater its vibratory rate. With this theory as a working hypothesis, and the idea that light travels 186,000 miles per second of time, I made an estimate of the vibratory rate of each color motion in its action upon the photographic plate, thus disclosing the descrepancies between high light vibrations and those which promoted indistinctness in the negative. By interposing a thin pale straw-colored glass between the lens and the object photographed, all colors of a high vibratory rate were reduced to greater harmony. In indoor photography, I recommended flooding the sitter with some suitable color. Still another way is to attach a pasteboard tube to the camera lens, and flood the inside with some selective color, through which the color vibrations have to pass. I have employed every shade and tint of colored glass I could get. I obtained some remarkable results with fluids for a screen. A glass receptacle made of thin white flint glass an eighth of an inch for the fluid; the receptacle wide enough and equally long to cover the lens. Transparent fluids of different chemical density give astonishingly varied results.

I was the lecturer for the National Photographic Association at the time I refer to, and I think the SCIENTIFIC AMERICAN had a reporter in attendance. At that time I made the statement that "if the principles of molecular radiation were true, the time was not far distant when we could be able to photograph the internal human anatomy." I also said that "disease as a mode of motion in some of its phases could be photographed in consequence of its action upon the epidermis." This has been done, and is done.

The striking similarity between your reproduction of Prof. Wood's experiments and several out door photos made by my experiments, elicited my attention; and although I have no copies of my work in that line at hand, I am still deeply interested in any discovery that extends the lines of scientific research. I do not know how recently Prof. Wood made these investigations, but I want you to know that an American practically covered this ground, and much more, thirty-five years ago. You may recall me as one of your contributors in an essay upon "The Fourth Dimension of Space."

Buffalo, N. Y. DR. W. M. LOCKWOOD.

Nitrogen and the Soil

To the Editor of the SCIENTIFIC AMERICAN.

In the issue of your paper dated July 1st, there appears on page 9 an article entitled "An Important Contribution to the Nitrogen Problem." This article refers to a bulletin published by Lyon and Bizzell of Cornell University, and entitled "A Heretofore Unnoted Benefit from the Growth of Legumes." I am writing now to correct an error, since the priority of this discovery belongs to the New Jersey Experiment Station. A preliminary statement of these experiments is made in the annual report of the Office of Experiment Stations, United States Department of Agriculture, for the year 1909, page 150. A copy of this report may be secured from the director of the office at Washington.

A fuller statement of these experiments was submitted to the *Journal of Agricultural Science*, published at Cambridge, England, in the summer of 1909. After much delay this paper was published in the fall of 1910. The paper in question is abstracted in the Experiment Station record for April, 1911, page 423. The inclosed copy of this paper will show you that the problem was solved in a very exact manner by a method devised at the New Jersey Experiment Station.

I should feel indebted to you for calling attention to this fact in the columns of your paper.

JACOB G. LIPMAN, Acting Director.

New Brunswick, N. J.

The Moving Picture and the Psychology of the Chauffeur

To the Editor of the SCIENTIFIC AMERICAN:

I like your comment on the article in your paper, "Psychological Apparatus for Testing Chauffeurs," and would like to suggest that the complicated signaling system could be done away with by substituting a moving-picture machine. It ought to be possible to make suitable films for the purpose, with means for throwing the recording apparatus in motion, at the instant the person to be tested sees the picture on the screen.

Jewell, Ohio. H. G. PANNING.

Testing Chauffeurs with the Moving Picture Machine

To the Editor of the SCIENTIFIC AMERICAN.

I was interested in reading Automobile Novelties. It doesn't seem to me that the signals for danger and different degrees of danger is a very fair test to the chauffeur, as he would have to be very familiar with the different signals before he could control his machine as well and as quick as he could under the conditions the signals represent or indicate. Now the moving-picture machine is perfected to such an extent, that the actual reproduction of danger can be produced in a most realistic manner, and it seems to me that by this means the test would be a far fairer one, as the chauffeur would have only his machine to think of, and in some emergencies this is a great plenty. It also seems that to put a real machine instead of the dummy would be an improvement, as it is well known that all men familiar with moving machinery of all kinds have a sense of feel that is highly developed, and would tend to put the chauffeur more at ease, as it would be more like the real thing.

Orange, Texas. F. T. RITTER.

The Knight Valveless Engine

By F. G. Sterling

IN THE usual automobile poppet valve the poppet or mushroom valves are lifted from their seats by cams and reseated by springs In a four-cycle motor, the valves in each cylinder are opened and closed once in two revolutions of the crank shaft This intermittent movement of the valve must be produced by a cam and a spring mechanism The valve is not closed until it is in actual contact with its seat Hence the valve must be free to seat itself under the action of the spring Noise is produced when the cam strikes the valve to lift it, and also when the spring strikes the seat and starts to close the valve. This noise in itself indicates a tendency to wear In the usual construction there is no way to provide for wear Furthermore, neither cam nor spring is suitable for high speed work While the poppet valves work well at low speeds, they are unreliable at high engine speeds, and the "timing," or opening and closing of the valves, is uncertain. This is the gravest objection to the poppet valve By a radical change in design, Charles Y Knight of Chicago has produced a design of valve for the four-cycle internal combustion motor, a design in which all the inherent disadvantages of the poppet valve are eliminated

For some time prior to 1908, Mr Knight manufactured and marketed in small quantities an automobile called the "Silent Knight" The claim for silence lay in the motor Although successful enough, the car, owing perhaps to lack of detailed refinement and the use of the new motor, did not appeal to the automobile trade Knight, whose chief interest was in the motor itself, thereupon took his invention to England, and succeeded in interesting the English Daimler Company in it After many tests and further development and refinement the English firm adopted it

Almost immediately the engine became the subject of much discussion and investigation by British automobile and technical societies, culminating in an exhaustive test by the Royal Automobile Club As a part of this test a 38 horse-power motor (4¾ inch bore and 5¼ inch stroke) was run continuously for 132 hours under a load of 54 horse-power The motor was then placed in a chassis and driven for 2,000 miles on the famous Brooklands track Next it was returned to the testing rack and run for five hours more and developed 57 horse-power Under the conditions of this test the load on the testing rack was never to be less than 1.3 times the calculated horse-power of the motor The road test was to be made at a speed of not less than 40 miles per hour and the final return of the engine to its bench test was to determine its final condition

These extraordinary conditions of the test were insisted upon by the Daimler Company and the final bench test was especially desired by them The reason is apparent when it is noted that the horse-power developed was in excess of the power developed at the start of the test, both tests being at the same engine speed—1,200 revolutions per minute

Evidently the Daimler Company reasoned that while it might be possible for a poppet valve engine to meet the first and second stages of the test it was obviously impossible for such a motor to meet the final stage, i e, to develop more power, to be in better condition after continued running After the motor had successfully withstood the test, the Daimler Company was awarded the Dewar trophy and the motor received the unqualified official indorsement of the Royal Automobile Club's technical committee.

Extensive tests and experiments have been made on the motor in this country, with the result that three American firms have secured licenses. In a few years the new motor will be as well known here as it is abroad.

The motor is not really valveless, nor is it in any way akin to the two-cycle motor. Knight's invention is a mechanical or structural improvement in the design of the valve mechanism.

The valve mechanism consists of two concentric sleeves sliding up and down between the piston and cylinder walls. Certain slots in these valves register with one another at proper intervals, producing large and direct openings into the combustion chamber from the exhaust and inlet ports in the cylinder The sleeves are operated by small connecting rods from a small crank shaft or eccentric shaft running at one-half the speed of the main shaft

Fig 1 shows the general arrangement of the parts and their nomenclature The detail operations of the valves can best be seen by a glance at the seven diagrams comprising Fig 2. In the diagrams the relative positions of the inner and outer sleeves at various points in the cycle of the motor are indicated The method of reciprocating the sleeves by connecting rods from the eccentric shaft is shown The eccentric shaft is positively driven, by a silent chain, from the main crank shaft and rotates at one-half the speed of the motor The eccentric operating the inner sleeve is given a certain advance or "lead" over that of the outer sleeve This lead, together with the rotation of the eccentric shaft at half the crank shaft speed, produces the cycle of operations

In the first diagram the piston is just past its top center, and is starting down on its inlet stroke The inner sleeve is at the bottom of its travel and moving slowly upward, the outer sleeve is about midway in its travel and is moving downward rapidly The opening from the carburetor through the inlet port into the cylinder is a rapidly increasing space between the upper edge of the slot in the inner sleeve and the lower edge of the slot in the outer sleeve By the time the piston is a little more than half way down on the suction stroke the inlet passage is wide open as shown in the second diagram of Fig 2. The outer sleeve is now at the bottom of its stroke and moving very slowly, the inner sleeve is gaining in speed moving upward, and the inlet is closed by the lower edge of the inner sleeve slot in passing the upper edge of the outer sleeve slot, as shown in the third diagram of Fig. 2 The inner sleeve continues to move up with the piston on its compression stroke, the rings in the head and piston tightly sealing the compression space, until the explosion occurs. The sleeves and piston are then in position shown in the fourth diagram. About two-thirds of the way down on the explosion

(Continued on page 176.)

What Railroad Accidents Cost

ALTHOUGH the railroad companies take every possible precaution to avoid wrecks, the newspapers constantly report more or less serious accidents. Few of us realize what a money loss almost every one of these entails. Some figures on the wreck of the Brewster Express on the Harlem division of the New York Central and Hudson River Railroad, published in a recent number of the *Railway Employees' Magazine and Journal*, prove that any expense for prevention is economy.

That wreck occurred near Woodlawn, February 16th, 1907. Without including damages to equipment, loss owing to delayed traffic, and other things, the damage claims and other expenses paid and in process of settlement cost the road $1,214,000. Of this, $659,000 was paid in claims, and the balance was for lawyers' fees, fees to agents who settled claims out of court, physicians, investigators, and experts, and for trial suits

The largest amount paid for a single death was $75,000; the smallest $5,000. The average was $13,824 Eighteen of the twenty-two victims were women, eleven of them unmarried, which reduced materially the damages the company had to pay, though several of the single women were bread-winners.

Among the injured, the highest damages awarded were $32,500 to a young woman whose left leg was amputated This verdict has been appealed by the company Settlements for injuries have ranged from $1,000 upward.

The History of the Present Cholera Epidemic

THE following data, taken from the French publication *Larousse Mensuel*, regarding the cholera epidemic, of which we have recently felt some of the distant manifestations, may be of seasonable interest The epidemic took its origin in India in 1902, and was carried to Hedjaz by the Hindoo pilgrims on their way to the rituals at Mecca The disease was thus carried to Egypt, and in 1903 to Damascus, in 1904 to Bagdad, whence it crossed Persia and the Caspian Sea, reaching Baku and the mouth of the Volga The cholera then spread in the Caucasus (three thousand cases in Russia), and in 1905 appeared in Poland (six hundred cases), whence it entered eastern Prussia and appeared in a number of places in Germany (three hundred cases) In 1906 little was heard of the epidemic, but in 1907 it carried off thirteen thousand victims, starting from southern Russia and ascending up to St Petersburg in 1908 (thirty thousand cases) The plague continued its ravages in the domain of the Czar, and put forth a finger as far as Constantinople In 1909 a number of foci of infection appeared in Russia (twenty two thousand cases) and the disease made its appearance in several towns of Holland (sixty cases, mainly at Rotterdam) and of Belgium (nine cases), whither it was carried by ships Forty cases were also recorded in eastern Prussia Every winter the epidemic appears to die out, then it gradually resumes activity In 1910 there were 281,259 cases (131,433 deaths) in Russia, especially in the southern provinces.

This great outburst resulted in a number of isolated cases in Germany and Austria, and in numerous cases observed since the month of August in southern Italy. The disease was carried there by a number of Russian emigrants who left ship at Brindisi In this way 127 localities were infected The balance sheet for the epidemic shows 11,700 cases, with 768 deaths. In Turkey also the disease made great ravages, of which, however, no statistical records are available.

Mode of Propagation.—Inasmuch as the period of incubation of the disease lasts only six days, any healthy individual who has been out of contact with any infected person for a period exceeding six days, used to be considered innocuous, and incapable of carrying contagion. It has, however, been observed that a person may very well carry microbes in his body, and disseminate the same without being himself affected. Hence arises the necessity of examining the dejects not only of diseased but of healthy persons, as far as they may have been exposed to contagion. In Holland the rigorous application of this principle has reduced the number of fatal cases to four. While cholera may be generally contracted by contaminated drinking water, it may also be acquired through the ingestion of fruit and vegetables grown near the surface of the soil and watered with contaminated water. We may carry on our shoes and garments from the street into the houses portions of mud containing microbes, and upon brushing off such stains we distribute through the air dust and microbes which may fall upon food materials and thus enter the body

Preventive Measures.—Of these the first and the chief is naturally the strict supervision of immigrants, sailors, and similar persons That these are the carriers of the disease, and not the river water itself, is shown beyond question by the fact that the epidemic proceeds up the streams, against the current The second precaution consists in careful attention to the proper disposal of waste matter and disinfection of the same, so far as persons afflicted with the disease are concerned, and the exclusion of flies. The food and drink and medicine for the sick person should be kept carefully covered. Water and milk should be boiled before drinking, and in fact only cooked products should be eaten, which moreover should be carefully protected from access of flies Vegetables and raw fruit should be allowed to stand for half an hour in a three per cent solution of tartaric acid, and then washed with boiled water. Care should be taken not to partake of any foods (melon, unripe fruit) which irritate the intestines, so that the body may not be predisposed to offer a breeding ground for microbes.

The Motor Truck in the Country

THE *Engineering News* recently expressed the opinion that one use for the motor truck to which it would be difficult to place a limit is in direct haulage over considerable distances to safe an intermediate railway journey Direct deliveries may be made by automobile from a city wholesaler to his customers in towns twenty or thirty, or even forty, miles away at less cost, perhaps, than would be involved in the hauling to the railway station and hauling from station to receiver at the other end of the route, when the various rehandlings that are made necessary by the railway shipment are taken into account The saving in cost of packing alone, where this method of delivery is used, may often make its adoption worth while.

"There are large possibilities also in the use of motor-propelled vehicles in industrial plants, shops and warehouses in place of the industrial railway or the overhead carrier, both of which systems are in extensive use," continues the *Engineering News* "With present-day shop floors of concrete or wood-block paving, motor trucks can be run over them with little more friction than over the rails of shop tracks A great advantage over the rail system is that the trucks can be run anywhere There is no stoppage for turntables or switches or because of cars blocking the line ahead as happens so often with industrial railways In such a system, where current for charging is available at low cost and where the loads to be hauled are light, storage battery trucks appear to have great promise The extent of this one field alone is so great that it will tax the ability and enterprise of many engineers and many manufacturers to adequately cover it"

Varieties of Whales

FEW of us realize that the blue or sulphur bottom whale found in all our oceans is not only the largest animal which lives to-day, but is also, so far as is known, the largest animal which has ever existed on the earth or in its waters A writer in the *National Geographic Magazine* states that specimens have been measured which reached the length of 87 feet, and in all probability weighed as much as 75 tons Although the mouth is enormous, large enough, in fact, to permit ten or twelve men to stand upright in it, the throat measures only about 9 inches in diameter

"The finback, closely related to the blue whale, has been called the 'greyhound of the sea,' for its long, slender body is built on the lines of a racing yacht, and the animal can equal the speed of the fastest steamship. The back is dark gray, shading into beautiful light gray on the sides and pure white below. A noticeable characteristic about this whale is the symmetry of the throat coloring; the left side is dark slate and the right pure white like the under parts The baleen also, on the right side, for a distance of about 2½ feet, is white, in sharp distinction from the remaining dark plates

"The humpback is the most interesting of all our large whales, partly because of the fact that its habits are more easily studied than are those of the other members of the family Its maximum size is under 55 feet, but its body is thick and heavy, with enormous side fins, or flippers These great paddles are one-quarter the length of the entire body, and a single one from a whale 49 feet long weighed on the station scales 956 pounds The throat breast, flukes and flippers of the humpback are almost invariably covered with masses of barnacles, or rather barnacles on barnacles, for the hard, shell like Coronula are themselves the hosts of the soft pendant goose barnacles"

In Japan, the writer of the *National Geographic Magazine's* article studied the Sei whale of the Norwegians, which is the 'Iwashi kujira' (sardine whale) of the Japanese It is not a large animal, seldom exceeding 54 feet, and is formed on slender, graceful lines, much like the finback Its coloration also resembles in a general way the latter species, but it can readily be distinguished by its high, falcate dorsal fin The Sei whale has a habit of swimming just below the surface, sometimes with the dorsal fin exposed and when feeding will travel for a considerable distance in this manner It is a difficult whale to shoot, because the back is arched but slightly when the animal dives, and only a comparatively small part of its body is shown above the water at one time

It is stated that the distance traversed by whales when beneath the surface of the water depends entirely upon circumstances The longest period of submergence for finbacks, actually timed by watch, was twenty three minutes, but there is little doubt but that most large whales can remain under water a considerably longer time

Most extraordinary of all whales is the square-nosed sperm whale Instead of having plates of baleen, this whale carries a row of 20 to 25 heavy teeth on each side of the lower jaw These fit into sockets in the roof of the mouth, and assist in holding the giant squid and cuttle fish on which the enormous animal feeds Since the squid seldom gets far out of the warm currents, the sperm does not go into the cold water, but cruises about in the tropics and in the Gulf of Japan streams

In the upper portion of the head the whale has an immense oil tank in which the valuable 'spermaceti' is found in a liquid condition, and from which it may be dipped out with a bucket when an incision has been made From a sperm whale 60 feet in length which was sent to the American Museum of Natural History from Japan 20 barrels of spermaceti were taken out of the "case" and the surrounding fat This oil congeals as soon as it is cooled by the air, but the natural heat of the body keeps it in a liquid condition until the case is opened

The sperm whale is the animal which yields ambergris, the valuable substance used so extensively in the manufacture of our best perfumes Ambergris is only found in "sick" whales, that is, its presence is not normal, but is caused by a pathological condition of the intestines It has been found floating upon the water, and is also taken from the intestines themselves after the whale has died or has been killed It is used as a vehicle for perfumes, and not as an odor itself

Abolishing the Postage Stamp.

IN our day the mail traffic of large business concerns has swollen to gigantic proportions, and even the simple labor of affixing stamps requires a special clerical staff No wonder, therefore says the *Limehau*, "if the problem has been considered how the stamp could be abolished altogether without prejudice to the interests of the post office Proposals of this character have not been wanting, as for instance in Bavaria, since February 1st, 1910, large consignments are simply stamped with a postmark at the post office, the operation being carried out by machinery In this way the post office has saved the expense for paper and the printing costs for ten million stamps, while the business world has economized time and money, for affixing stamps to one thousand letters requires about an hour and a half of time

"This method of treatment, while fairly satisfactory, is still primitive We can easily imagine a much better system worked out somewhat along the lines of a gas or water meter, the letter being simply placed in a machine, and stamped with a postmark which serves at the same time as receipt for the postage and as record of the date, etc The machine would be inspected periodically by the post office in just the same way as the consumer's gas or water meter is inspected, and his bill would be paid as usual"

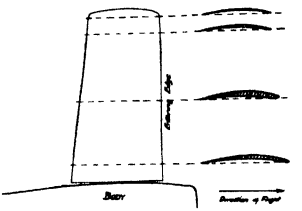
Lessons of the 1911 International Cup Race

Comparative Features of the Types

By Grover Cleveland Loening, B.Sc., A.M., C.E., Author of "Monoplanes and Biplanes"

THE third race for the "Grand Prix" of aeroplaning the cup and prize created by James Gordon Bennett—was held at Eastchurch, Isle of Sheppey, on the 1st of July.

The first race—that won by Curtiss in 1909 was over a distance of 20 kilometers. The following year the race, held at Belmont Park, for a distance of 100 kilometers, was won by Grahame-White. The distance this year was increased to 150 kilometers.



Curtiss' victory in 1909 was a splendid one, and well earned, the race of 1910 can but be described as a "fluke." Although the steady flying of Grahame-White won him much sincere praise, the unfortunate accident to Leblanc robbed him of the prize in the moment of victory.

This year's race, however, far surpasses previous contests, in the brilliancy of the flying and the highly instructive and satisfactory results given by it. The best talent of three of the greatest manufacturing concerns—the Blériot, the Wright, and the Nieuport—was set to the task of producing not only the speediest creation but one that would outwit its rivals in maneuvering and reliability. The monoplane proved itself the most adaptable type for speeding and the biplane the most easily controlled, the perfection of "banking," landing, and steady flying exhibited by the diminutive Wright, attracting much favorable comment.

The order of finishing and the official elapsed time of the contestants follow. Weymann (U. S. A.), 1 hour 11 minutes 36 1/5 seconds; Leblanc (France), 1 hour 13 minutes 40 1/5 seconds; Nieuport (France), 1 hour 14 minutes 37 3/5 seconds; Ogilvie (England), 1 hour 19 minutes 10 2/5 seconds. Chevalier and Hamel, the former on a Nieuport monoplane and the latter on a Blériot monoplane, started in the race but did not finish.

Weymann flew a Nieuport monoplane, and made an average speed of just 78.1 miles an hour. Leblanc on his Blériot later averaged 75.91 miles an hour, Nieuport on a monoplane of his own make attained an average of 74.94, while Ogilvie made 71.2 miles an hour, including time for a stop. The latter's speed of flying not considering the stop was 84 miles an hour.

Nieuport's speed was rather surprising in view of the record he made at Mourmelon on June 16th with the same 70 horse-power monoplane—100 kilometers at a rate of 80.24 miles an hour. Difference in atmospheric conditions might account for this.

Sections of the plane of the Nieuport monoplane.

Section of Plane - WRIGHT

Section of Plane - BLERIOT

Details of Planes.

The astonishingly small difference in speeds between the 30 horse-power Nieuport of Chevalier, the 70 horse-power Nieuport flown by its designer, and the 100 horse-power Nieuport of the victorious Weymann is a very noticeable fact and one deserving of the closest study.

The victory was primarily one for the Gnome motor and the French aeroplane industry in general, giving only a small insight into the enormous leadership France holds over the rest of the world in the development of the aeroplane. By no stretch of the imagination can the victory be said to be one for America except on what might be classed a technicality. Weymann not only flew a French machine equipped with a French motor but received his flying instruction in France under the tutelage of French experts.

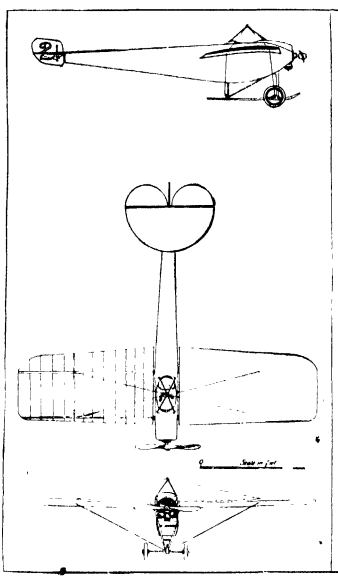
Those who are pluming themselves on the great victory for America have therefore cause to hesitate.

May the contest of 1912 exhibit a more pronounced example of Yankee industry.

This race is the first from which concrete and valuable conclusions can be drawn, and its results point to many advantageous features that should be introduced into the next Gordon Bennett race to make it a means of stimulating greater perfection and of representing the highest achievements in aeronautical engineering.

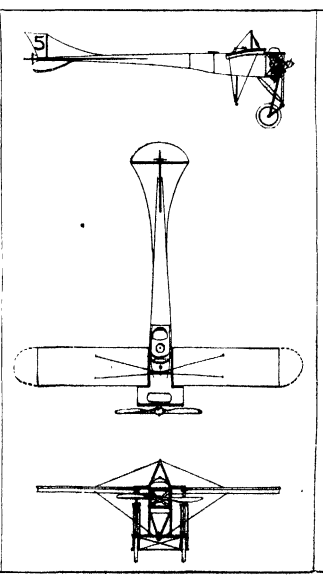
Before pointing out important deductions obtained from a study of the machines and their performances, a brief description of each is given, accompanied by plans and elevations drawn to the same scale, thus enabling a graphic comparison to be made.

THE NIEUPORT MONOPLANE



The winning machine is a distinct type, bearing little if any resemblance to the almost standard types, the Blériot or Antoinette.

The most important features in its design are the profile of the wings, the great reduction of head resistance, and the exquisite form and proportioning of the various parts.



Weymann's Nieuport was equipped with a 14-cylinder, Gnome engine rated at 100 H.P. This drove at almost 1,500 R.P.M., a two-bladed Regy propeller, 7 feet in diameter.

This machine, due to its high power, appeared to the spectators to fairly leap into the air, and dart about with arrow-like swiftness and precision.

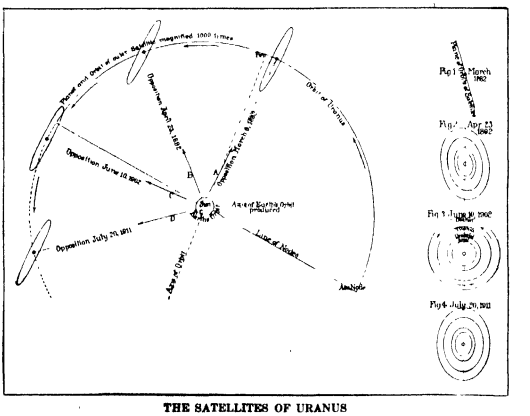
LESSONS OF THE 1911 INTERNATIONAL CUP RACE

The Satellites of Uranus

Moons That Have a Retrograde Motion

By Professor Frederic R. Honey, Trinity College

IN THE revolutions of the planets around the sun, and of the satellites around their primaries, there exists an apparent law of conformity to that general direction which is followed by our sun in its rotation on its axis But the fact that this conformity, though followed by a large portion of our discovered system, is not invariable, is emphasized by its contradiction in the retrograde motions of the ninth satellite of Saturn and of all the satellites of Uranus and Neptune. These apparent contradictions in planetary revolution have naturally given rise to much inquiry and speculation regarding the evolution of the solar system.



The four known satellites of Uranus, which revolve in a plane which is nearly perpendicular to that of the ecliptic, appear at their vast distance from us to have diameters varying between 500 and 1,000 miles The illustrations given in this article are for the purpose of emphasizing an example of departure from the general law of motion. The moons of Uranus, in contrast to their primary, revolve in a retrograde or backward direction—their orbital plane being just past the critical position of perpendicularity Notwithstanding the great distance of Uranus from the sun, which is more than nineteen times the earth's distance, the planet's diameter of 32,000 miles renders it visible as a star of the sixth magnitude which is of a light sea green color On account of the tilting of the earth's axis Uranus does not rise much above the horizon, and is seen to best advantage in northern latitudes during the summer months before and after opposition, which occurred this year on July 20th The period of revolution is 84 years; and as a consequence the planet comes to opposition between four and five days later each year—its synodic period (average interval between consecutive oppositions) being 369 2/3 days The plane of the orbit very nearly coincides with the ecliptic, forming an angle of only ¾ degree with it This is the smallest angle of inclination of the orbits of any of the major or terrestrial planets; while the linear eccentricity, or distance from the center of the orbit to the sun (82.5 million miles) is greater than that of any of the orbits This point is shown in the plot at C within the earth's orbit, and is about seven-eighths of the distance from the sun to the earth The angle of inclination of the plane of the satellites' orbits, which was measured in March, 1882, is less than 98 degrees The planet came to opposition on March 6th when approaching perihelion, but the plane of the orbits passed through the earth, and was seen edgewise, looking in the direction of the arrow *A*, about three weeks later, when the satellites appeared to move back and forth in a straight line (see Fig 1) The next edge view, when the plane of the orbits will again pass through the earth, will be obtained in 1924, that is after an interval of 42 years Fig 2 shows the orbits seen in the direction of the arrow *B* at the date of opposition April 23rd, 1892

During the years 1901, 1902 and 1903, the differences between the lengths of the axes of the ellipses representing the orbits on a plane perpendicular to the line of vision were so small that they were practically circular, showing the nearly perpendicular position of the orbital plane Fig 3 shows the orbits of the satellites *Ariel*, *Umbriel*, *Titania*, and *Oberon* as seen looking in the direction of the arrow *C* at the date of opposition June 10th, 1902 Since this date the minor axes of the ellipses have gradually contracted, and their positions looking in the direction of the arrow *D* on July 20th of this year are shown in Fig. 4. In each of these figures the position of the ellipses is shown relative to the meridian. These satellites revolve around Uranus (which is drawn to the same scale as the orbits) in the direction of the arrows. The distances from the planet and the periods or time of revolution are given in the table. In the plot of the orbit of Uranus the planet and the orbit of the outer satellite *Oberon* are magnified 1,000 times in order to show their relative dimensions, and the proportion between the axes of the ellipse which is the projection of the orbit on the plane of the ecliptic

	Distance in Miles	Period in Days
Ariel	120,000	2 52
Umbriel	167,000	4 14
Titania	273,000	8 71
Oberon	365,000	13 46

Treatment of Obesity

OBESITY is a disease of the general nutrition, characterized by a general hypertrophy of the adipose tissue, and an accumulation of fat in the organism "A rough rule," says *Cosmos*, "is that an adult's weight, expressed in kilograms, should be represented by the two last decimals of the figure which expresses his height in meters In a pretty severe case of obesity a person may weigh about 265 to 330 pounds. Barnum and Bailey exhibited an individual weighing 660 pounds. Heredity plays an important part in determining the occurrence of this morbid condition This has been observed both in men and in animals

THE SATELLITES OF URANUS

It is not every one who can accumulate body weight At the same time, given a certain predisposition, there are certain conditions which favor obesity, and certain modes of living and treatments which may reduce it or even cause it to disappear entirely

"Overfeeding, lack of exercise, in brief, an excess of the receipts over expenditures, favor obesity Nevertheless, there are stout people who eat very little, and there are hearty eaters who remain thin There must be some other element which enters into consideration The thyroid and certain other glands regulate all oxidation processes. The secretions of these glands intensify the oxidation, their degeneration tends to diminish oxidation The true cause of obesity is still a matter of considerable mystery Generally speaking, a special diet and mode of living is unquestionably the right remedy, and has frequently proved effective.

Some medical authors have recommended a veritable hunger cure; others impose a meat diet This last method is positively dangerous for arthritic patients, and may moreover be quite useless, since it is possible to fatten on a pure meat diet Other authorities have recommended the use of foods of low alimentary value, taken in considerable quantity, such as fruit, green vegetables, but no meat Others forbid drinking or recommend eating fat or butter in considerable quantities, thereby producing a species of satiety and destroying the appetite

"Such treatments as these are, as a rule, either harmful, or quite impossible to carry out for any length of time. A more rational treatment, it appears, has been proposed by Dr Robin, which is based on a number of seemingly well founded scientific arguments. The *régime* laid down is somewhat as follows (1) Breakfast at eight o'clock in the morning, consisting of a piece of meat, fowl, or cold ham, a small piece of bread (about fifteen grams), fresh fruit, and a cup of very weak and very hot tea, without milk and sugar, immediately after this meal take about at least half an hour's walk, but not enough to become tired or short of breath (2) At eleven o'clock the second meal, consisting of one or two boiled eggs, two pieces of bread and a cup of hot water flavored with a little tea, after this a walk as before (3) At half past twelve the third meal consisting of cold meat, cold chicken, ham *ad libitum* (without sauce or mayonnaise), a plate of green lettuce, or the like, with a little salt and lemon juice, a plate of green vegetables, boiled in salt water, without butter or gravy Fruit *ad libitum*, bread fifty grams For drink, a large cup of hot water flavored with a little tea Rise immediately after the meal and take a walk of at least half an hour (4) At half-past five, a large cup of hot water flavored with a little tea (5) At half-past seven the same meal as at noon, to which may be added, if the appetite is very keen, some cold fish, or a plate of hot meat without gravy This cure is continued until the weight is reduced, if not to normal conditions, at least to an improved state It is interrupted, if any indications appear that it is affecting the patient harmfully After the cure is terminated, the eleven o'clock meal is first of all omitted and then gradually the *régime* may be abandoned, proceeding with prudence and exercising greater rigor every time the weight is observed to increase

"It is stated that with the above treatment much improvement is secured without inflicting upon the patient any unpleasant feelings of hunger or weakness"

Cost of Building Cheops

IT HAS been estimated that to rebuild the pyramid of Cheops under modern conditions an expenditure of $100,000,000 would be necessary and the labor of 40,000 men for two years required

It has been calculated that the work really required the services of 100,000 men for thirty years

The pyramid occupies a space of twelve and three-quarter acres and is seven hundred and forty-six feet high and contains about 1¼,315,000 cubic yards of stone and granite The material alone represents an item of $36,000,000, while the labor would increase this amount by $72,000,000 To this must be added $3,000,000 for tools, transportation, and similar items

The pyramid is built on a solid rock one hundred and fifty feet deep, and to build a foundation of this character would add to the cost to the extent of making the total of $100,000,000

The Cry of the "Devil-bird"

OF all the awe-inspiring sounds emitted by wild creatures none, it is said, is to be compared to that of the "devil bird" of Ceylon, whose cry has been likened to the scream of a human being undergoing the most frightful torture Naturalists have identified this bird with the brown wood-owl found in Hindustan

The "devil-bird," or ulama, as the Cingalese call it, is an elusive creature The natives of Ceylon regard the cry of this bird with superstitious horror, for, it is claimed, its scream heard at night presages the most dire misfortunes

A British official of the Ceylon civil service has given some study to this curious bird Its ordinary note, he states, is a magnificent clear shout like that of a human being, heard at a great distance, and producing a fine effect in the silence of the night But the sounds that have earned for the bird its bad name, and which this officer reports he heard to perfection but once, are said to be well nigh indescribable the most appalling that can be imagined, and scarcely to be heard without a shudder It has been compared to the cries of a boy in torture, whose screams are being stopped by strangulation.

[The Editor of the Home Laboratory will be glad to receive any suggestions for this department and will pay for them, promptly, if available.]

Etching Metals by Electricity

By A. J. Jarman

THE etching of metals by electrical energy does not seem to have received the attention it deserves It must be borne in mind that wherever any chemical body is employed to perform etching, there also is electrical action

Many times when etching by electricity has been attempted, the protective top bearing the inscription has been eaten away before any appreciable depth has been attained This has been caused by the employment of an unsuitable etching fluid, or the protective top was not sufficiently resistant to the separated element or ion liberated by the electric energy By a little study of the chemical bodies employed for etching either copper, zinc or steel, such as nitric acid, perchloride of iron, sulphate of zinc, and chromic acid, it has been found that these bodies are not the best suited for electrical etching The real point to be considered is the effect of the liberated element upon the metal Several solutions have been found that will answer the purpose well, and it is safe to predict that in due time the etching of metals by electric energy will become universal, because by the employment of electricity, it can be as readily ascertained how far the etching has proceeded by noting the amperage and the time elapsed, or, in other words, *quantity* of electricity employed This, according to Faraday's law, is proportional to the quantity of metal dissolved By the *electrolytic* method one man could perform all the etching of six plates in the same time that it takes to etch one by the usual processes For the protective top, any of the preparations may be used that are employed at present for ordinary etching, such as albumen, fish glue, enamel or bitumen.

For the information of those who are not acquainted with the above preparations it may be stated that the following will give results that can be depended upon, bearing in mind that where water is mentioned, *distilled* water is meant at all times

SENSITIZING SOLUTION FOR ZINC

The white of one fresh egg (albumen)	
Distilled water	6 ounces
Bichromate of ammonia	20 grains

Dissolve the bichromate of ammonia in two ounces of the distilled water The remaining four ounces of water must be added to the albumen, which must now be well churned into a frothy mass for two or three minutes Add two *drops of strong* aqueous ammonia to the egg mixture, using the egg beater, then add the bichromate mixture, beat again well, add half an ounce of pure photographic alcohol, using the egg beater again, so as to insure perfect incorporation After the bichromate has been added to the albumen, the mixture becomes sensitive to light, and therefore all subsequent steps should be carried out in red light, or at any rate in subdued daylight Allow the mixture to stand over night, then filter it through a tuft of absorbent cotton pressed lightly into the neck of a clean glass funnel, placing a flat strip of glass into a wide mouth bottle diagonally under the tip of the funnel, so that the sensitive albumen mixture falls drop by drop upon the glass strip The object of this is to prevent the forming of air bubbles The filtering must be conducted under a deep orange colored light

If copper or steel is to be employed, the following mixture must be made

SENSITIZING SOLUTION FOR COPPER

Photo-engraver's fish glue	2½ ounces
Water	2½ ounces
Albumen (fresh)	¼ ounce
Bichromate of ammonia	50 grains
Water	½ ounce

Dissolve the bichromate separately add this to the fish glue and albumen The mixture must now be well churned by a rotary egg whisk or beater, then filtered as described for the zinc sensitizer, but preferably twice The etching solution must be made up, and kept in a glass battery jar The etching solution given here is a special mixture for *electrical* etching only

ETCHING SOLUTION.

A saturated solution of common salt, about	2 pints
Hydrochloric acid	2 fluid drachms
Water	5 ounces

This solution will keep well. The use of hydrochloric acid is to correct for the liberated sodium hydroxide which is formed by electrolysis; the liberated chlorine performs the etching, and combines with the zinc or copper, forming chloride of zinc or chloride of copper In the case of steel, perchloride of iron is formed. Each metal must be etched in a separate solution. It will be observed that, after etching, the solution for zinc will remain white, that for copper will turn green, and the solution for steel will become a brilliant yellow To perform the etching, an ordinary half-tone negative (reversed) must be employed, or for line etching an ordinary dense line negative, made by the wet collodion process

Procure a few pieces of zinc plate about one-sixteenth of an inch thick, the same as used by photo-engravers Carefully clean the plate by wiping it all over, back and front, with a warm solution of common washing soda Rinse the plate in clean water, and allow to dry This operation is simply to rid the surface of any greasy matter introduced by handling The plate

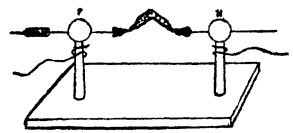


Fig. 1.—Electric etching in line on zinc.

First arc lamp, Sir Humphry Davy, 1808 From an old engraving, 1812.

must now be cleaned thoroughly, with fine pumice powder and water, by placing it face up upon a clean board, using a clean rag dipped into the pumice powder, and rubbing well up and down, not in circles. The plate must be reversed, so that the bottom end becomes the top, and the rubbing continued until, when washed with water from a faucet, the water will remain free and even all over, showing no greasy streaks or spots Now drain the plate after it is well washed in running water all over, and pour a small quantity of the sensitized albumen mixture (under an orange light) upon one end of the plate.

Fig. 2.—Michael Faraday.

Halftone electric etching on copper. From an old photograph.

Tilt it so that the water is driven before the albumen, and allowed to run off Drain the plate; then pour a small quantity of the sensitive mixture upon the opposite end and drain this off, allowing only a small quantity to remain upon the plate, which must now be gripped tightly at one corner by a pair of flat-nose pliers, and held level over the flame of an alcohol lamp, or small gas stove. Blow upon the surface with the breath, so as to aid evaporation of the water. Care must be taken that the plate does not become too hot, because this would cause the albumen to become insoluble. The plate now being dry, may be laid upon the negative, which has previously been placed in a photographic printing frame A piece of felt is placed upon the back of the zinc plate, the back adjusted, and the springs, which should be very stiff, hitched into place. The negative must be allowed to rest upon a stout piece of flat glass in the printing frame The frame can now be placed in the sunlight. If this is very bright, and the negative is a clear and brilliant one, the exposure will be about one minute and a half to two minutes The frame must now be returned to a room illuminated by a deep orange colored light, the zinc plate removed, laid back down upon a stout sheet of glass, and a small India rubber roller, which has been carefully rolled up with a small quantity of lithographic ink, is passed over the printed surface of the zinc, rolling from front to back. The plate may now be reversed, and rolled until the surface presents a uniform gray coating of ink all over Now place the inked plate into a tray of clean water, let it remain for five minutes, then take a tuft of wetted absorbent cotton, and carefully wipe the inked surface still under the water, when, if the exposure has been right, a beautiful print in minute dots or lines will present itself upon the surface of the zinc The plate must now be removed, washed under the faucet, and carefully dried, then powdered all over with dragon's blood, the excess being removed by tapping the back with a sharp blow of a hammer handle, holding hammer head in the hand. The surface must now be lightly brushed with a flat camel's hair brush and the plate heated over a gas flame, until it begins to smoke faintly Then lay it upon a piece of cold metal for about two minutes, when it will be ready for the etching bath Two cells of the zinc and kind described in the SCIENTIFIC AMERICAN of May 28th, 1910, page 445, will form the battery for generating the requisite electrical energy

The elements must be coupled in series, viz., the carbon of one cell connected by a piece of copper wire to the zinc of the next A piece of sheet copper, zinc, or brass must be soldered to a copper wire and attached to the zinc cylinder of the free element. This will form the cathode It must be remembered that electrical etching is the reverse of electroplating

The piece of zinc bearing the ink image must be brushed over every part that is not to be etched, with either shellac varnish or a thin coating of asphaltum varnish, which is best done when the plate is warm This protection will prevent the plate from being attacked, except where the required etching is to take place The plate must now be attached to the remaining carbon element of the battery, by simply soldering a tin or brass garter clip to the end of a strip of copper wire, the right kind of clip being one of those with saw-like teeth This will grip the plate perfectly, and allow easy removal The plate, now being firmly gripped, must be quickly lowered into the salt solution Instantly gas will be evolved from the cathode, while the metal exposed between the dots will begin to dissolve After two minutes' action the plate should be lifted and examined, when in nine cases out of ten it will be found to be satisfactory Dip the plate into the liquid again for three minutes, then remove it, and pour a gentle stream of clean, cold water over the surface Now use a biconvex lens of about four inch focus to examine the surface, when it will be found that for all ordinary printing purposes, the etching will be deep enough

The albumen top will hold well in this etching solution, because it is well known that albumen becomes coagulated in a strong solution of common salt If upon examination it is found that the etching is not deep enough, the plate should be very carefully brushed all over the surface with a flat camel's hair brush; then washed, dried and the ink roller carefully passed over the surface again, then warmed to partly set the ink, powdered again with dragon's blood, heated to melt this again, cooled off, and etched again for two or three minutes As a rule, this second etching is not required. The surface must *not* be rubbed with absorbent cotton, because the edges of the etch are very sharp, and the fiber of the cotton will adhere very tenaciously The plate may now be cleaned with either wood alcohol and ammonia, or if asphaltum has been used, benzine or turpentine must be employed to remove it When the plate is cleaned, it can be trimmed at the edges, and pinned to a wooden block to make it type high, fitted in with type in the usual way, inked up and printed. If the etching is to be done upon copper, the fish glue enamel must be used, because it is better suited for copper than the albumen resist. Procure a piece of sheet copper the same as used by photo-engravers, that has been faced, polished and buffed. Clean it in the same way as described for zinc. Use

Simple Patent Law; Patent Office News; Inventions New and Interesting

Electrified Artificial Rain for Agriculture

A New System of Irrigation

WE have had occasion in these columns to refer repeatedly to experiments carried on by Sir Oliver Lodge and others on the influence of electricity on the growth of plants. Mr. Emilio Olsson of Buenos Aires, Argentine Republic, at present in the United States, has, of late years, been giving his attention to the practical development of a process in which it is proposed to make use of electrified water for sprinkling fields. The inventor claims that his experiments demonstrate the practical utility of such a procedure. The benefits which are said to be secured are two-fold. First, there is a direct advantage to the plants, and secondly, Mr. Olsson states that according to his observations various harmful insects and other organisms are destroyed because of his process.

The need of artificial irrigation is severely felt in many places where, owing to the nature of the climate, long terms of drought have to be contended with. It is particularly in such districts as these that Mr. Olsson proposes to introduce his system, by the aid of which he expects to increase the crop and to combat effectually drought, insects and other troubles. The cost of the Olsson system is estimated at a figure which is quite moderate as compared with the benefits to be derived. The cost of installation for the sprinkling apparatus is figured at $50 to $100 per acre, according to local conditions.

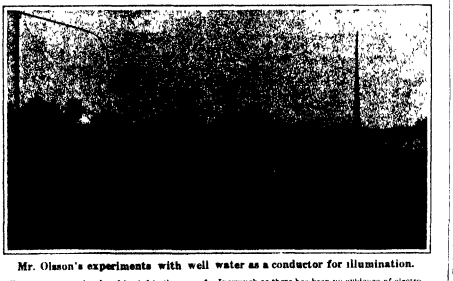
The system is very simple. The water is raised to a suitable height by a motor or traction engine. The supply may be drawn from a river, stream, artesian well, or any other suitable source. Two high towers may be installed, from which pipes are suspended by means of suitable supporting cables. The pipes supply circular spray nozzles which revolve automatically, and five to ten acres of land can readily be thus supplied with an evenly distributed shower of water.

When it is desired to use electrified water, a reservoir is used, into which the water is pumped, to be subsequently distributed in the manner indicated above. The reservoir consists of an iron tank placed on an insulated support and charged from a dynamo supplying 0.5 ampere at 110 volts. The iron wall of the tank serves as positive pole, the negative pole consists of a copper wire insulated all except the tip. It is claimed that certain chemical reactions take place in the water, with production of oxygen, ozone, and hydrogen peroxide at the anode, and that certain of the products formed are beneficial to the plants. Mr. Olsson further suggests that this electrification of the water would tend to purify it and render it better adapted for drinking purposes.

Mr. Olsson has installed his apparatus in a plantation near Buenos Aires and states that by the use of six sprinkling nozzles at a height of 5 meters above ground some six hundred acres of ground under cultivation were treated with very beneficial results. The apparatus has also been adopted by the municipality of Buenos Aires and is giving satisfaction in the public parks and gardens in that city. Mr. Olsson also states that during the long drought from which the republic suffered for over six months in 1910, he was able to produce a very fine crop of alfalfa and vegetables and to supply the owners of race horses with fresh fodder. By installing a system of artificial irrigation over some part of their crop, farmers should be able to insure themselves against drought, falling back upon artificial sprinkling in case natural rain fails.

Incidentally the interesting suggestion is made that the water line be used at the same time to carry the current for lighting and other purposes.

Mr. Olsson's invention has been protected by a number of patents, and the inventor has shown much perseverance in working out the details of his method.



Swedish Milking Machine

A MILKING machine has been developed in Sweden which imitates the process of hand milking as nearly as possible, that is by compressing the teat *from top to bottom*, but without drawing down upon it. Each teat enters a small metal box in which is a fixed rubber plate lying along one side of the box, while a movable rubber sheet is driven forward by two pistons, lying one above the other, so that the pressure is made first by the top piston and then by the bottom one, as in hand milking, or ten such machines for milking one hundred cows in two hours, where seven or eight milkers would be needed for hand milking. The animals do not seem to object to the machine and keep quiet during the operation.

Irrigation by means of electrified artificial rain.

In this new application of electricity, plant growth is stimulated by electrified water.

Mr. Olsson's experiments with well water as a conductor for illumination.

The pipes are insulated and buried in the ground. Inasmuch as there has been no evidence of electrolysis, Mr. Olsson believes that the electrolytic destruction of water pipes may thus be prevented.

After this, the pistons are thrown off by an automatic device and the process begins again. A funnel-shaped rubber bag takes the milk and it flows from here into a containing vessel of suitable shape. There is one front and one rear milking box and these are held in a forked support which is strapped to the animal. The rubber plates and bag are the only parts to come in contact with the milk and these can be very easily cleaned, so that there is no difficulty about this part. Any kind of an air compressor is used to operate the pistons and it is driven by electric motor or gasoline engine or even by horse drive. The air pipes are led along the stables and at each stall is a fitting upon which a rubber tube leading to the milker is placed. Two milkers can take care of eight

Notes for Inventors

An Automatic Elevator-door Lock.—The Otis Elevator Company, as assignee of Axel Magnuson of New York city, has obtained a patent for operating apparatus for the locks of elevator doors, No. 998,624. The latch is associated with the door and its operating device is separate from and independent of the car and is automatically operated only when the car is opposite or near the door.

Westinghouse Turbine Patents.—George Westinghouse of Pittsburg has obtained patent No. 998,820 for turbine-blading, and No. 998,821 for a condensing-turbine.

The turbine-blading includes in connection with the rotor having annular rows of blades, the stator, the blade carrying elements and circumferentially extending rows of stationary blades on the elements, the elements being mountable on the stator. The condensing-turbine is a re-entrant turbine in which the casing is divided into a stationary part and a cover and the fluid discharge devices are located entirely in the stationary part.

Coin-handling Machinery.—In a coin-handling machine, patented No. 998,830, to Universal Coin Wrapping Machine Company of New Jersey, as assignee of Chas. S. Batdorf of Brooklyn, is provided means for adjusting the coin-advancing and coin-wrapping mechanism to agree with the size of the coins to be wrapped and with the length of the packages.

A Peculiar Laminated Propeller.—Spencer Heath of Washington, D. C., has patented No. 998,897, a bladed propeller, consisting of interior laminations of soft wood and exterior lamination of hard wood, with hard wood portions forming the extremities of the interior laminations.

Hair Washing Hoods.—Most women resent the difficulties and inconveniences incident to the washing of the hair by the ordinary processes. Orlando B. Salisbury of New York city has obtained two patents, Nos. 998,803 and 998,804, for hair-washing hoods. He provides a hood to fit the head and neck sufficiently large to inclose the hair and supplied with suitable means to admit and discharge the water and lathering, on its interior, flexible fingers, which may be manipulated from the outside to aid in the washing operation.

An Old Patent on Cooling Houses.—Now that the subject of cooling dwelling houses in hot weather has attracted general attention largely through the ingenious efforts in that direction of Dr. Alexander Graham Bell at his Washington residence, it may be worth while to call attention to a patent, No. 246,781, issued in September, 1881, and now expired, to R. S. Jennings of Baltimore, Md., for an air-cooling apparatus which provided a cooling chamber having screens of fibrous materials arranged longitudinally and vertically and which, in practice, were moistened with a cooling liquid. The apparatus presented in this patent has a special interest since it was used in cooling the White House during the hot period when the wounded President Garfield lay suffering from the assassin's bullet, and the descriptive portion of the patent refers to "the use of the hereinbefore described apparatus at the Executive Mansion, Washington, District of Columbia."

Patents to Corporations.—Among the patents issued July 25th, 1911 are five patents and one reissue to the United Shoe Machinery Company, and eight patents to the General Electric Company.

A Negro Patent Examiner.—Henry E. Baker of Mississippi is the only representative of the colored race in the examining corps of the United States Patent Office. Mr. Baker is a second assistant examiner in the division of Principal Examiner Pond, who has the classes of bridges, hoisting, excavating, hydraulic engineering and metallic building structures, which includes, of course, structural iron working, and all allied arts. Mr. Baker, in addition to his duties in the Patent Office, is engaged in the compilation of a work in which he will be absolutely unique. He is the only individual who has a complete list of all the patent issued to negroes, and it is his purpose to embody them into a work of some sort probably a book, giving a brief history of each inventor, the nature of the invention and the amount of success in the field of invention achieved by members of his race. The compilation of these statistics has necessarily been an arduous one, and has required an exhaustive correspondence with applicants and inventors in all parts of the globe. Naturally, many colored inventors fail to offer any evidence as to the race to which they belong as that is not a requirement made of an applicant for patent. But through the courtesy of attorneys and the aid of his fellow examiners Mr. Baker has been able to gather together what he considers is practically a complete catalogue of inventions by colored persons.

Billings Lectures on Patent Law.—The Hon. Cornelius C. Billing, First Assistant Commissioner of Patents, has accepted the invitation of the president of the Washington College of Law to deliver a series of lectures on Patent Office practice, before the classes of that college. Mr.

Billings is thoroughly conversant with every phase of procedure within the Patent Office. He commenced his career in the capacity of assistant examiner and has occupied every position in the office at one time or another. He became principal examiner by due course of advancement, was law examiner, examiner of interferences, acting examiner of trade-marks and designs, and a member of the board of examiners-in-chief. The present commissioner selected him for the position of assistant commissioner, and when the office of first assistant commissioner was created by Congress to meet the growing demands of the judicial branch of the office, Mr. Billings received the appointment. During the absence of Commissioner Moore in South America for four months in 1910, Mr. Billings was acting commissioner, so that the statement that he has filled every office in the Patent Office is specifically true.

Considering the duties which he discharges in his present place, in the hearing and deciding of appeals in patent cases, which decisions are final so far as the Patent Office is concerned, there is no doubt that his course of lectures at the Washington College of Law will be of the greatest interest and value.

A Commission for Supervision of Patents.—The Minnesota Electrical Association and the St. Louis section of the American Institute of Electrical Engineers have adopted resolutions petitioning President Taft to urge in his message to Congress the establishment of a permanent commission or department of the government for the supervision of patents and similar properties. It is thought that the functions of the Patent Office, as at present organized, stop short of that point where they could be of the greatest value to inventors, owners of patents and stockholders all over the country. The Patent Office has no control over patents after they are granted, and the electrical organizations named above, while recommending the establishment of a commission to supervise patents, trade-marks, etc., do not contemplate the robbing of the Patent Office of any of its existing functions. Rather there is a desire to increase those powers. Whether or not such a commission would savor of paternalism, it cannot be denied, but if, as contemplated, it should exercise a power somewhat similar to those of the Interstate Commerce Commission, much good might be accomplished in the business world. The preservation of the rights of inventors, manufacturers and investors through a supervisory board or commission would in all likelihood be preventive of fraud and infringement to a large degree.

Phonographic Advertising.—An advertising device, having an advertiser exhibitor and a phonograph to announce the advertisement as it is displayed, is shown in a patent, No. 998,721, to George A. Stafford of Belchertville, Texas. It has a motor which, through suitable mechanism, operates to display advertisements successively and the motor also operates the phonograph to announce the advertisements.

Putting Out Gasoline Fires.—In our issue of July 15th, we stated that there was not yet a fire extinguisher especially adapted to put out fires "accompanied by the burning of gasoline or resultant gases." A manufacturer calls to our attention his own product which is widely advertised, and which consists in excluding oxygen and preventing combustion. His is what he calls the "gas blanket" principle, applicable to all kinds of fires, even those of electrical origin. The substance which he uses is an absolute non-conductor with a dielectric strength of 500,000 volts per cubic inch.

Legal Notes

The Chartreuse Liqueur Case.—The Supreme Court in an opinion delivered by Mr. Justice Hughes, has confirmed the right of the Charthusian monks in the well-known trade-mark for liqueur or cordial. In reciting the facts, so far as the Court deemed it necessary to state them, the decision says that:

For several hundred years prior to 1903—save for a comparatively brief period following the French Revolution—the order of Carthusian monks occupied the monastery of La Grande Chartreuse near Voiron, in the Department of Isere, in France. This was their Mother House. There, by a secret process, they made the liqueur or cordial which, at first sold locally, became upwards of fifty years ago the subject of an extensive trade and is known throughout the world as Chartreuse. The monks originally manufactured the liqueur at the period following the French Revolution—the order of Carthusian monks occupied the monastery of La Grande Chartreuse near Voiron, in the Department of Isere, in France. This was their Mother House. There, by a secret process, they made the liqueur or cordial which, at first sold locally, became upwards of fifty years ago the subject of an extensive trade and is known throughout the world as Chartreuse. The monks originally manufactured the liqueur at the period following the French Revolution, when they were driven out and later at Fourvoirie, close by. It was marketed here and abroad, in bottles of distinctive shape, to which were attached labels bearing the inscription "Liqueur Fabriquee a la Cde. Chartreuse," with a facsimile of the signature of L. Garnier, a former Procureur of the order, and its insignia, a globe, cross and seven stars, and these symbols, which "Cde Chartreuse" underneath, were also ground into the glass. In 1878, the then Procureur registered two trade-marks in the Patent Office, and these were re-registered in 1884 under the act of 1881. In the accompanying statement the one was said to consist "of the word 'Chartreuse,' accompanied by a facsimile of the signature of L. Garnier," and the other "of the word-symbol 'Chartreuse' and the combinations in which these were used were described."

In the year 1903, having been refused authorization under the French law of July 1st, 1901, known as the Associations Act, the congregation of the Chartreux was held to be dissolved by operation of law, and the monks took steps to their properties in France by a "sequestrating administrator and liquidator," appointed by the French Court. Forcibly ejected from their former establishment, and taking their secret with them, the monks set up a factory at Tarragona, in Spain, and there, according to their ancient process, they have continued the manufacture of the liqueur, importing from France such herbs as were needed for the purpose.

The French liquidator, Henry Lecouturier, employing a skilled distiller and chemical assistants, undertook, by experimentation, to make at Fourvoirie a liqueur, either identical with, or resembling as closely as possible, the famous "Chartreuse" and having succeeded in this effort to his satisfaction, he placed his product upon the market under the name.

The liquidator's cordial was shipped to this country and sold by the agents of the liquidator the same description and with the same marks and symbols which had been used by the monks, if there was any difference, it is frankly stated to have been unintentional.

On final hearing the Circuit Court held that the registered marks constituted good and valid trade marks and the sole and exclusive property of the Charthusian monks or fathers. The Circuit Court of Appeals affirmed the decree with some modifications which affect only the paragraph containing the injunction.

In considering the argument that the mark is a geographical name, Justice Hughes says:

If it be assumed that the monks took their name from the region in which they settled in the eleventh century, it still remains true that it became peculiarly their designation. And the word "Chartreuse" as applied to the liqueur, which for generations they made and sold cannot be regarded in a descriptive sense as a geographical name. It had exclusive reference to the fact that it was the liqueur made by the Carthusian monks at their monastery. So far as it embraced the notion of place, the description was not of district, but of the monastery of the order—the abode of the monks—and the term, in its entirety, pointed to production by the monks.

In considering the effect upon the U. S. trade-mark rights of the liquidation proceedings in France, the decision, after referring to certain House of Lords and Court of Appeals proceedings in the related case in England, says:

If through his experiments, the liquidator had not succeeded in making a liqueur which resembled that of the monks, he would have had no business to transact so far as the liqueur was concerned, and the transfer by operation of law would not have availed to give him one. But the property in the trade-marks in this country did not depend upon the success of the endeavors of the liquidator's experts. The monks were enabled to continue their business abroad, and still had the process and, continuing it, they enjoyed all the rights pertaining to it save to the extent to which by force of the local law they were deprived of that enjoyment in France.

The decision has a special interest in its bearing upon so-called geographical marks, for, after citing Canal Company v. Clark, 13 Wall. pg. 324, Columbia Mill Company v. Alcorn, 150 U. S. 460; Elgin National Watch Company v. Illinois Watch Company, 179 U. S. 665, the Court says:

"The familiar principle, however, is not applicable here," and points out that "so far as it embraced the notion of place, the description was not of a district, but of the monastery of the order; the abode of the monks—and the term in its entirety pointed to production by the monks."

Recently Adjudicated Patents.—Out of ten adjudicated patents reported in the Patent Office *Gazette* of July 25th, 1911, eight patents were sustained by the courts, and infringement was found in four cases. One of these was in the case of the Gillette razor patent, No. 775,134, in Gillette Safety Razor Company v. Clark Blade & Razor Company (C. C.) 187 Fed. Rep. 149.

RECENTLY PATENTED INVENTIONS.

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Pertaining to Apparel.

GARMENT.—S. TREBEL, New York, N. Y. This garment is for use for bathing, athletic and other purposes, and is provided with an integral jockstrap, which can be conveniently opened and closed and when worn is practically concealed and not visible. For the purpose mentioned use is made of a suspensory band extending from the back of the garment and having its free end detachably connected with the free ends of straps or webbings attached to the rear of the garment.

Electrical Devices.

ELECTRIC BRAKE.—W. F. MOODY, Denver, Colo. This brake is of the kind provided with a flexible brake band. The invention provides in connection with the band a rocking member whose ends are connected with the ends of the brake band and braking force is applied to its middle portion, so that when the brake is set the position of the rocking member is changed by the tension of the brake band; one end of the rocking member acts for the moment as a fixed pivot and the opposite end pulls upon the opposite end of the brake band, so that the rocking member operates as a lever of the third class, and applies braking force effectively, with least expenditure of force.

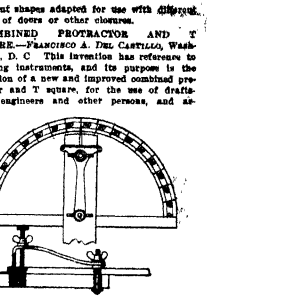
Of General Interest.

DECK LASHING DEVICE FOR LIFE SAVING APPLIANCES.—F. EIRKEEN, 3 Tuffel bays Alle, Copenhagen, Denmark. This device is for the lashing of life-saving appliances, such as life-boats and the like, well lashed to the deck, so as not to be swept overboard in a heavy sea, are so much the more difficult to release and it takes a longer time to do so the greater the firmness with which they are lashed to the deck. The invention has for its object the device that the boat or raft is safely fastened to the deck, but released automatically if the ship sinks, whereby the boat or raft floats.

CABLE CLAMP.—C. A. BUTLER, Bartlesville, Okla. This invention provides a clamp for quickly and readily attaching a releasing cable, provides removable jaws and special gripping jaws for varied employments, the jaws being universal for mounting in the clamp, provides jaws arranged for a multiplicity of adjustments to accommodate the use in conjunction with tables constructed of different materials, and provides an apparatus having an auxiliary clamp and holding device for the second line or cable.

ROCK LOOSENING AND IMPREGNATING DEVICE.—P. TRIPKE, Dortmund, Germany. This invention consists of a device adapted to tamp a bore-hole made in any rock or coal-stratum and to force any quantity of water pressure from an end portion of the bore-hole through the faults and crevices in the rock or coal stratum for bringing down or loosening the rock, while the water is prevented from escaping directly through the bore-hole to without.

FEED MEASURING APPARATUS.—J. J. SMITH, West Hoboken, N. J. The purpose here is to insure accuracy and economy in feeding stock, and to enable the quantity to be varied at any instant, yet made always definite and certain, so that on those days when draft animals are working a full feed for the day may be readily measured, while on Sundays or other days of rest a smaller feed may be measured with equal certainty and with the same facility.



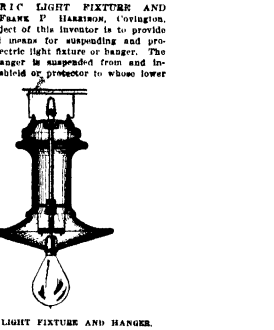
WHISTLE.—A. W. PROCTOR, New York, N. Y. This invention relates especially to whistles of the kind used as toys, the more particular purpose being to give the whistle such form as to facilitate its being held in position by aid of the lips and teeth of the operator. Further it relates to means whereby the sound may be so modified as to simulate the throbbing call of a bird, the throbbing to some extent under direct control of the operator.

PHOTO ENGRAVING DEVICE.—G. A. LEBEAU and H. R. THERESER, Nashville, Tenn. An object here is to provide means whereby a negative having a better detail may be produced. A further object is to provide means for obtaining good strong solid dots in the blacks of the negative in a minimum of time. The device is simple in its nature and inexpensive.

Hardware and Tools.

LOCK.—RAFFAELE PERLA, 2 East 120th Street, New York, N. Y. The object of this invention is to provide a lock which serves the purposes of the ordinary padlock, which, when in position, prevents the staples or eye-bolts from being filed or cut, and which renders difficult other unauthorized methods of opening the lock. His further object is to provide a lock in which the lock bolt proper is operated by key-controllable mechanism of the pin-tumbler type, which permits of a large number of vibrations on the key-controllable mechanism, and which may have the casing of different shapes adapted for use with different kinds of doors or other closures.

COMBINED PROTRACTOR AND T SQUARE.—FRANCISCO A. DEL CASTILLO, Washington, D. C. This invention has reference to drafting instruments, and its purpose is the provision of a new and improved combined protractor and T square, for the use of draftsmen, engineers and other persons, and arranged to permit of setting the blade of the square to any desired angle indicated by the protractor or to accurately fasten the blade in right-angle position relative to the base of the protractor. For the purpose mentioned in the foregoing use is made of a protractor (illustrated herewith), at the center of which is pivoted a blade, and an arm extends from the pivot of the blade and is provided with spaced pins straddling the sides of the blade, the pins also engaging apertures in the protractor.



COMBINED PROTRACTOR AND T SQUARE.

Heating and Lighting.

ACETYLENE GAS GENERATOR.—L. E. BOSTROM, Ormond, Fla. The object of the invention is to provide a simple and efficient feeding device for acetylene gas generators, by means of which the carbid will be fed in small amounts to the generator whenever the pressure in the generator falls below a predetermined level.

ELECTRIC LIGHT FIXTURE AND HANGER.—FRANK P. HARRISON, Covington, Ga. The object of this inventor is to provide an improved means for suspending and protecting an electric light fixture or hanger. The fixture or hanger is suspended from and inclosed by a shield or protector to whose lower portion a lamp socket and a reflector may be conveniently attached. The details of construction, arrangement and combination of parts are illustrated in the accompanying engraving which represents a central vertical section of a lamp fixture and hanger constructed in accordance with the invention. The several parts of the interior portion are easily detachable from one another, which facilitates storage and transportation.

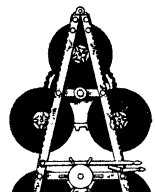
ELECTRIC LIGHT FIXTURE AND HANGER.

Household Utilities.

ATTACHMENT FOR INVALID BEDS.—JOSEPHINE M. SWANSON and T. S. OLSEN, New York, N. Y. The object here is to provide a bed which is inexpensive and simple, and which may be used as a foot rest or a seat to support the patient when the bed is raised, and the patient in an inclined position; as a back rest; as a table, as a protector to prevent an unconscious or delirious person from injuring himself against the head of the bed; and as a cradle for supporting the weight of the bed clothes.

Machines and Mechanical Devices.

UNIVERSAL RUDDER FOR FLYING MACHINES.—W. KRIMOWA and W. BOUSSON, New York, N. Y. The more particular purpose here is to provide a rudder for service upon flying machines; that is to say, a rudder having a vertical movement for controlling altitude and a horizontal movement for controlling direction relative to the points of the compass—the rudder having surfaces disposed at different angles for assisting movements of the rudder to be effected.



SEWING MACHINE.—J. L. KRAKOWSKY, New York, N. Y. In this instance use is made

of a thread case adapted to contain a spool of thread and a loop-taking hook mounted to oscillate on the peripheral face of the case to take hold of the needle thread loop and to carry the loop sufficiently far around the case for finally casing of the loop to form a lock stitch in conjunction with the spool thread

TRIP MECHANISM FOR WELL SINKING MACHINES.—H. H. HAIGHT, Winnebago, Minn. This invention provides a mechanism for use in conjunction with the jerk line or drop cable used in a well sinking machine, provides a pulley for the said cable arranged to regulate the extent of the take-up of the cable, and provides a construction for the pulley and mounting therefor which is durable, simple and efficient.

DRIVING GEAR.—J. L. KLEINMAN, New York, N. Y. In this patent the invention has reference to pedal-actuated driving mechanisms, and the object is to provide a new and improved driving gear more especially designed for use on sewing machines and the like, and arranged to convert the oscillating motion of the pedal into rotary motion without undue exertion on the part of the operator.

BELT RACK.—ROBERT L. SMITH, Ninth and M Streets, Lincoln, Neb. The belt rack illustrated herewith in an end elevation occupies little room and carries many belts which may be readily moved to the desired position to permit of being unrolled. The device is constructed so that the belting is prevented from slipping from the spindles by the frame of the

BELT RACK.

device, it being possible to move the spindles to a position at which the belts can be readily moved. Means provide for locking the operating parts so that the spindles with belting may be held on a predetermined position relatively to the frame. Means provide for retarding rotation of the spindles carrying the belts. Also means by which rolls of belting may be wedged there around.

Prime Movers and Their Accessories.

PACKING.—P. S. TIRRILL, deceased; MAUD M. HEATH, Administratrix, care of Heath-Clark Co., Lyndonville, Vt. The object in this invention is to provide a packing, especially adapted for use with turbine engines, to prevent the escape of steam around the shaft, and also to prevent the entrance of air when the first stage pressure is below the atmospheric pressure, and which will not require any great amount of skill to fit, and when in place will not injure the shaft by cutting

STEAM TURBINE.—J. BLAKSLEE, New York, N. Y. An object here is to provide a turbine with a rotor, to which the steam is admitted at the periphery and exhausted at the center, the rotor comprising a plurality of stages having gradually increasing steam passages advancing from periphery to center, with abutments increasing in size from periphery to center, so that the operating fluid, such as steam, as it decreases in pressure will have increased abutting surface to impinge on, thereby maintaining the turning moment uniform throughout the rotor.

MECHANISM FOR GOVERNING EXPLORIVE ENGINES.—H. DE LAVALETTE, 175 Avenue de Choisy, Paris, France. According to this invention the governing arrangement acts on the two valves to once which are both operated; when the speed exceeds a predetermined limit a lever is automatically engaged by a centrifugal governor in such a position that it keeps the exhaust valve constantly open notwithstanding the action of its return spring and prevents the admission valve, which is normally closed by action of another spring, from being opened by the controlling mechanism.

Railways and Their Accessories.

DUMP CAR.—T. WALKER, Paris, Ky. In this invention use is made of a truck, a platform thereon, receptacles mounted to repose on the platform, means for raising the inner ends of the receptacles to tilt the same, aprons hingedly and adjustably mounted on the platform and adapted to slidably receive the material dumped, and auxiliary aprons for removable attachment to the said aprons

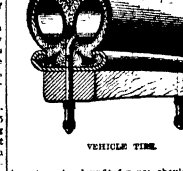
Pertaining to Recreation.

GAME APPARATUS.—M. F. SHEA, Newport, R. I. This invention relates to games and has for its object to provide a device to be used as a counter or indicator with other games of chance or hazard. For this purpose use is made of a shell provided with a series of designating characters and a disk mounted to revolve in the shell when the shell is gyrated, the said disk having thereon an indicating pointer

GAME PIECE.—C. SCHUTZ, New York, N. Y. This invention has reference to game pieces, the inventor's more particular purpose being to provide a game piece adapted to slide along a smooth surface, such as that of a board or table the game piece being provided with a base and a rotund upper portion revolubly relatively to the base

GYROSCOPIC TOP.—J. F. O'BRIEN, Jarbridge, Nev. The present invention includes several novel features and improvements in gyroscopic tops, one relating to the construction of the shell or hollow sphere in which the gyroscope proper is inclosed, another being the construction and arrangement of the trunnion bearings for the gyroscopic wheels. The sphere will have on its exterior a delineation of a map of the world

Pertaining to Vehicles.



REFILLABLE BRAKE BLOCK.—J. H. SHELDON, Spokane, Wash. This improvement pertains to hollow or refillable brake blocks for use on wagons, or in places where a brake is customarily used. It provides an efficient brake block whereby surfaces may be replaced from time to time as they wear down. This is attained by positioning in a hollow frame or shell wooden blocks which may be replaced from time to time

APPARATUS FOR BRAKING VEHICLES.—LOUIS BOIRAULT, 20 Rue Lafitte, Paris, France. This invention has for its object an apparatus for braking of the kind in which the application of the brake shoes to the wheels is obtained by the action of a cam fixed to the axle of a pair of wheels and acting upon an operating lever which is caused to approach or separate from this cam in accordance with requirements

PUNCTURE CLOSING DEVICE FOR PNEUMATIC TIRES.—A. SMITH, Stuart, Neb. In applying the device to a pneumatic tire for the purpose of closing the edges of a rent, slit or puncture, the edges are drawn up together, and the device is slipped over the same, so that the body portions lie on opposite sides of the slit and below the same. The device is then compressed and thereby clamped firmly in place by means of suitable pliers, the edges of the opening being thus clamped together and closed air tight

SPRING WHEEL.—J. B. DUNLAP, Tulsa, Okla. In this construction of wheel an ordinary wheel may be employed, and a rim is arranged around the wheel proper and spaced therefrom, and springs are arranged between the wheel proper and the spaced rim, and the springs are so connected with both the wheel proper and the rim as to secure an efficient resilient connection between the wheel proper and the rim, so as to avoid rigid connections which would tend to crystallization.

VEHICLE TIRE.—JOHN W. DRISCOLL, Box 143, Central City, Colo. This invention is an improvement in pneumatic tires, and has in view a tire having pneumatic tubes so arranged that the chances of puncture are remote, each tube being separate and independent of the other tube, so that the tire

VEHICLE TIRE.

is not rendered unfit for use should one tube be deflated, a tongue being provided between the tubes and arranged to serve as a support for the tread under such conditions. The body of the tire is constructed of the usual materials, such as rubber, canvas, etc. The illustration herewith shows a perspective view of a portion of a tire embodying the invention, the same being shown applied to the rim of a wheel and in cross section.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

NEW BOOKS, ETC.

INDUSTRIAL PLANTS. Their Arrangement and Construction. By Charles Price Day, New York: Engineering Magazine, 1911. 8vo, 294 pp. Price, $3

Careful study of the lay-out and construction of industrial buildings is the primary step toward efficiency and economy in manufacture. Industrial Plants is the outcome of Mr. Day's wide experience as consulting engineer in the construction of some of the most successful shops and factories in the country. His analyses follow a scientific method which takes into account not only the mere material factors of the problem, but which also looks ahead to the complexities introduced by the human elements—the employes upon whom environment exerts so powerful an influence toward good or bad work, mental or physical. In this phase of the problem the field of the new "scientific management" is invaded. The discussion progresses from the broad general principles of lay out and arrangement to a consideration of detail as required in specific instances. Charts, diagrams, and inserts point the lessons set forth. Further chapters bear upon the relationship between client and engineer, in "characteristic modern examples" several large factories of varying types are pictured and described, and modern construction and painting are shown in their relations to adequate lighting. A large insert of a hat factory has red and blue routing lines showing the sequence of operations in the manufacture of hats. Metal-working shops are given considerable space, and the considerations bearing on machine-drive are featured in diagrams. The work will well repay a careful reading

THE MUTATION THEORY. By Hugo de Vries. Vol. II. Chicago: The Open Court Publishing Company. 600 pp., numerous illustrations, 6 colored plates. Price, $4

It was our privilege to review, shortly after its publication, the first volume of this work, which is destined to take its place beside Darwin's "Origin of Species." That first volume was devoted to an elaborate discussion of experiments made by Prof. de Vries with Lamarck's evening primrose, and from the experiments made the conclusion was deduced that species may arise suddenly rather than by that age-long process for which Darwin argued. In the second volume, De Vries shows where the accepted Darwinian theory is wrong and where it will be necessary to substitute his own mutation ideas. Darwin himself foresaw the mutation theory, for he distinguished between the multiplication of his "pangenes" and their modification, and saw that without variation "natural selection could do nothing." With Darwin, variability of any kind supplies the field in which selection works and sinks to quite a subordinate position in comparison De Vries on the other hand, holds that specific characters do not arise by selection. An old-fashioned biologist may not be inclined to accept the mutation theory and the modern biologists are certainly in favor of it; he has at least shown the necessity of experimental study of species

BUILDING FOR PROFIT. By Reginald Pelham Bolton. New York: The De Vinne Press, 1911. 8vo, 15 pp. Illustrations

In this book the reader will find a effort to present scientifically the conditions which surround the planning, construction, and operation of a wide variety of metropolitan buildings during the last fifteen years. Here will be found the methods of analyzing and deciding values of improved real estate from the metropolitan standpoint, so that the investor may know what fundamental principles he may safely observe, what conditions and methods will assist him in deciding upon the preliminary proportions of a structure in advance of expenditure, what factors must be considered in deciding on rates of depreciation, and what considerations must be weighed in rebuilding. The author has reduced his subject to mathematical relation to its parts, as far as possible, and has reported to diagrams in order to afford ready reference to results. The subjects of the seven chapters which constitute the book are the following: I, Relation of Site and Building; II, Appreciation of Value of Land; III, Value Established by Building; IV, Depreciation of the Value of Buildings; V, Depreciation of Mechanical Equipments and Power; VI, Cost of Operating Buildings; VII, Manufacturing or Power Machinery

CONSERVATION OF SANITATION. By Ellen H. Richards. New York: John Wiley & Sons, 1911. 8vo, 305 pp. Price, $2.50

Compiled from the experiences of the past twenty years, "Conservation by Sanitation" takes the position that sanitation is as much a paying proposition as a railroad or a machine shop. It concerns itself with three of our greatest modern needs: good air, good water, and the disposal of wastes. Under the present system of tight buildings, good air is by no means "free." Air supply costs the modern householder one-fourth as much as his food supply, although its charges are disguised under the names of "rent" and "fuel." The average man perhaps finds it easier to realize the good and evil potentialities of water. The author's facts and figures in relation to water supply—its efficiency, protection, and regeneration are abundant and convincingly marshaled. The interdependence of town and county is graphically shown in the panoramic view of a stream's pollution. Succeeding chapters are devoted to waste and means of purifying water and disposing of contaminating wastes. In conclusion we are given a series of laboratory notes dealing with air and water tests and determinations. The volume is put forth as a laboratory guide, but it has a simplicity, sincerity and readableness rarely found in the exposition of scientific subjects and the writer never loses sight of the ultimate object of her mission to the welfare and advancement of the masses

SCIENCE FROM AN EASY CHAIR. By Sir Ray Lankester, K.C.B., F.R.S. New York: The Macmillan Company, 1911. 423 pp., 84 Illustrations. Price $1.75 net

The volume before us is a collection of papers contributed by Sir Ray Lankester to the London *Daily Telegraph*. The modern thirst for scientific knowledge can be met better satisfied than by scientists themselves if they will only take the trouble to write down to the level of the great reading public. To be sure, popular treatment usually means such simplification of expression that it is difficult to maintain strict scientific accuracy. It is given to but few men to teach the multitude scientific truths in a way that the multitude can understand. If we may judge from this collection of essays Sir Ray Lankester may be numbered among these. His essays are all of them so simply worded that any man with a high school education can understand them. The variety of subjects is great, ranging as it does from biology to astronomy from meteorology to chemistry from paleontology to "death rates"

THE SUGAR INDUSTRY OF MAURITIUS. A Study in Insurance, Including a Scheme of Insurance of the Cane Crop Against Damage Caused by Cyclones. By A. Walter, F.R.A.S. London: Arthur J. Humphreys, 1910. 8vo, 228 pp., illustrated

The work is in the nature of an investigation into what the author terms the correlative coefficients between the cane crop of Mauritius and the meteorological elements. The investigation is naturally under two headings. First as to a method of estimating the damage caused by cyclones etc. and, second, a consideration of insurance against such damage. Matters have now progressed to the point where not only is capitalist insurance of the crop possible, but also an insurance of the profits. A brief history of the agriculture and commerce of the island is included

HOW TO GROW VEGETABLES AND GARDEN HERBS. A Practical Handbook and Planting Table for the Vegetable Gardener. By Allen French. New York: The Macmillan Company, 1911. 8vo, 312 pp., illustrations. $1.75 net

This is a new edition of the book previously published under the title "The Book of Vegetables." The writer confesses that at the earlier stages of his career as a market gardener he made many mistakes, some with costly mistakes and failures, and such a reference book as this book in his possession. The seasons and methods given are for the northern United States and the intimation is that of New York. Such vegetables as are of local interest and its uses given after which such points as soil, moisture, proper planting distances, and methods of handling are taken up. There is a table showing seed lengths, and ounce values, and an index giving immediate access to any desired information

MODERN GEOGRAPHY. By Marion I. Newbigin, D.Sc. New York: Henry Holt & Co., 1911. 12mo, 256 pp., Illustrated. Price, 75 cents net

"Modern Geography" is one of the issues of the Home University Library of Modern Knowledge, a commendable effort to continue the educative work of the serious magazine article. After a short review of the beginnings of modern geography surface relief and the process of erosion is studied, together with ice and its action. Climate and weather is the subject of another chapter followed by studies in plant geography and animal life. This brings us to the most interesting division of the little volume: that dealing with the races of Europe and their origin. A discussion of minerals and their distribution in relation to industries and towns fittingly concludes the body of the work. A descriptive list of works of reference is an adjunct to be commended

LA VITA MECCANICHE. Loro Calcolo e Costruzione. Manuale Teorico Pratico ad Uso dei Capi-officina meccanici Industriali, Capitecnici, Ingegneri Insegnanti di tecnologie meccaniche nelle Scuole Industriali e d'arti e mestieri, Tornitori, Fabbri, Alunni di Scuole Industriali. Milan: Ulrico Hoepli, 1911. 12mo, 215 pp., 110 cuts, 48 tables

The title and the subtitles form a sufficiently eloquent notice of the little work, which has the clear print and profuse illustration that distinguish the Hoepli handbooks

William Napier Shaw

(continued from page 163)

For a decade and more the most promising investigations in meteorology have been those relating to the exploration of the upper air. Accordingly, we find that Dr Shaw has taken a leading part in securing to Great Britain the enviable position she now holds in the field of aerology. I need only refer to a recent publication of the Meteorological Office. The Free Atmosphere in the Region of the British Isles," a large part of which was Dr Shaw's individual product, to illustrate his and the office's activity in this field.

Another recent development of meteorology is the discovery of striking correlations in atmospheric conditions at points on the earth's surface far remote from one another. Dr Shaw has within this branch of the science, devoted special attention to the relation borne by the southeast trade wind to the other currents of the general circulation, and to the secondary phenomena connected with them. This led him a few years ago to the discovery of a remarkable parallelism between the fluctuations of this wind and those of the rainfall in southern England.

To the present writer meteorology appears to be just now entering upon an era of much enhanced prestige, due to circumstances that may be stated in the following syllogism: Aeronauts must cultivate meteorology. We shall all soon be aeronauts. Ergo we must all cultivate meteorology, which henceforth must be looked upon as one of the most useful and important branches of science. Conversely, meteorologists must turn their attention to the problems of aeronautics. The director of the Meteorological Office is a member of the Advisory Committee on Aeronautics appointed in April, 1909, by the British government. The membership of the committee includes some of the highest scientific talent of England, with Lord Rayleigh as president. To its admirable report for 1909-10 Dr Shaw contributes four memoirs on meteorological topics of interest to aeronauts, and in these memoirs he shows how fully he realizes and how unreservedly he accepts the new tasks of meteorology.

Besides the textbook of physics already mentioned, and scores of scientific papers and reports Shaw has written a book on heat and one on ventilation. On the latter subject he is probably the highest authority in England, and he has been called upon from time to time, to report on the ventilation of various public buildings, including the House of Commons. In recent years he has found time to deliver a number of lectures on meteorological subjects—as reader in meteorology at the University of London, and in other capacities—some of which are about to be published in two volumes entitled "Forecasts of Weather" and "The Climates of the British Possessions."

His academic honors include the LL.D of Aberdeen 1906, Sc.D., Dublin, 1908, Sc.D., Harvard 1908, and Sc.D., Manchester 1910. He is an honorary member of the Meteorological Societies of Austria, Germany and Mauritius. In 1908 he was president of Section A of the British Association. In 1909 he attended the installation of Lowell as president of Harvard University representing his college Emmanuel, which was also the alma mater of John Harvard. In 1910 he received the Symons gold medal of the Royal Meteorological Society.

The Knight Valveless Engine

(continued from page 164)

stroke of the motor the exhaust passage begins to open. The inner sleeve is moving down with the piston, and the passage is between the lower edge of the inner sleeve slot and the lower edge of the junk ring in the head, the outer sleeve being practically stationary at the top of its stroke. The outer sleeve starts on its downward stroke and, gaining in speed as the inner does, leaves a clear opening for the exhaust. The piston is now one third up on its exhaust stroke, and the passage is closed by the upper edge of the outer sleeve slot in passing the lower edge of the exhaust port in the cylinder as the piston reaches its top center. The four cycles or strokes of the engine: suction, compression, explosion, and exhaust) have now been completed; the crank has turned twice, the eccentrics have driven the sleeves once, and the cycle of operation is now ready to be repeated.

The timing shown is not different from that ordinarily used in poppet valve engines. Any timing of the valves can be secured, however, by varying the "lead" between the eccentrics that operate the two sleeves and by properly locating the slots in the sleeves. The amount of valve opening is practically unlimited and is governed by the width of slot in the sleeves and the "throw" of the eccentrics that drive and determine the travel of the sleeves.

This valve area need not be much greater than that of a poppet valve. The equivalent of increased valve area is gained, however, by the directness of the valve openings and the absence of restrictions in the gas passages made possible by this construction.

The fourth diagram of Fig 2 shows that the compression space is contained entirely within the inner sleeve and that the fit or clearance between the sleeves has no effect either on the amount of the compression or upon the tightness of the compression space. The diagram also shows the general shape of the combustion chamber. It is evident that a minimum amount of surface is presented for the volume contained, so that the ideal spherical shape desired in gasoline motors is approximated.

The simplicity of the entire valve mechanism is apparent. The number of parts are few. All the working surfaces are cylindrical and consequently capable of easy and accurate machining. The bearing surfaces are large and easily fitted, and with a fair amount of lubrication should last indefinitely. The operation and movement of the parts present no new principle in mechanics.

The operation of these sleeve valves is absolutely quiet, accurate, efficient, and absolutely independent of the speed of the engine, which last feature is in great part responsible for the improved performance of Knight automobile motors.

A test of two motors identical except for the valve mechanism will show a certain decided increase in power in the sleeve valve motor, an increase in power which becomes more and more apparent as the speed of the engine increases. At low speeds the difference is not noticeable, for the cam and spring operated valves are then at their best. At high speed, however, the action of the poppet becomes very uncertain and the "timing" is uneven. The sleeve valve is not affected by high speed. The resistance offered to the passage of exhaust and inlet gases by the shape of the poppet valve openings is far greater than that of the sleeve valves. This limits the power output of the poppet valve motor.

Continued use of the Knight motor seems to improve it. The sliding sleeves apparently lap themselves into a better working fit. The lips of the slots in the sleeves remain clean and no difficulty in the lubrication or cooling of the motor is likely to develop.

The lubrication is generally effected by a splash system. In other words the oil is lifted from the base of the engine by the connecting rods and thrown upon the walls of the piston and sleeves. The sleeves are generally provided with a number of oil grooves, and the oil is lifted both by the wiping of the surfaces and the suction of the motor.

The cylinders are cooled by water. The usual centrifugal pump circulates water through the water jacketing of the cylinder and down into the water-jacketed head.

The motor here shown is of 4¼-inch bore by 5½-inch stroke. The travel of the sleeve is 1¾ inch.

There are now upward of six thousand of these Knight type motors in successful operation and their development and manufacture in this country will be watched with interest.

Lessons of the 1911 International Cup Race

(Continued from page 170)

The central frame, very deep at the front and of a significant fusiform shape, is entirely covered with fabric, reducing the air resistance immensely but adding in skin-frictional resistance. The shape of the body in section is rectangular, thus giving a large area of vertical and horizontal surface to aid in turning and in maintaining any given direction. Weymann and the other Nieuport pilots were able to negotiate the sharp turns with more ease in a calm than in a wind but were never able to attain the degree of "banking" repeatedly exhibited by the Wright. The large area of "directive" surface given by the body, would prevent any such sharp pivoting as is obtainable with the Dayton product.

The shape and sections of the plane are given in the diagrams. The entering edge of the plane profile is smooth and lacks any pronounced dipping. The plane is thinnest at the outer ends and thickest near the center of each wing—a curious feature that adds considerably to the strength.

The disposition of the seat in the frame and the shape of the rudders and tail are evident. The fixed semicircular tail surface is non-lifting and in fact is at a slight negative angle when the machine is in full flight. The two semicircular flaps at the rear of it constitute the elevation rudder and are operated by the forward-back motion of a large control lever. This same lever, when moved from side to side, operates the small single rudder for direction situated at the extreme rear.

The most noticeable and admirable feature of the entire design is the extreme reduction in the number of stay wires and projecting spars. Outside of the body the only source of pure head-resistance is a four-piece mast to which the planes are braced and the simple chassis. The latter consists merely of a strong ash frame and skid and two wheels mounted on a laminated steel spring—a magnificent combination of simplicity, utility, and strength.

The planes are double surfaced, 28 feet in span and with a chord measuring 6 feet 10 inches at the body, gradually decreasing to 5 feet 8 inches at the tips. The plane is warped for transverse control by means of a foot yoke actuating the inclined rod appearing on the chassis and to the ends of which the warping wires are attached.

The entire length of the machine is 25 feet.

The surface area of the supporting plane is in the neighborhood of 150 square feet. The weight with operator and fuel as flown in the race was nearly 700 pounds. This gives a loading of 4.66 pounds per square foot. The aspect ratio is roughly 5 to 1.

Weymann flew his Nieuport tail-high at an extremely low angle of incidence, often 1 degree or less—an interesting and suggestive fact.

THE BLÉRIOT XXIII.

This racing type of Blériot flown by Hamel and by Leblanc was originally about 22 feet in span. But at the last moment M. Blériot deemed it wise to clip the ends of the wings, finally reducing the span of the machine used by Leblanc to almost 17 feet. The chord of this type measured 3½ feet, so that the surface area was in the neighborhood of but 60 square feet! This is less than the area of the elevation rudder, alone, on the old 1909 Wright biplane.

The appearance presented by this machine was in consequence little short of ridiculous. At the front end of the long tapering frame was mounted the 100 H.P. 14-cylinder Gnome engine driving a Rogy propeller, the same kind of power plant used by Weymann.

Major Squier once defined the limit of the aeroplane as a helicopter flying horizontally; M. Blériot is evidently aiming for this goal—with what success remains to be seen.

The entire length of the apparatus was about 24 feet. The rudders at the rear and the warping were operated by the usual Blériot "cloche" and pedal system.

The weight with aviator aboard was nearly 550 pounds, thus giving a loading of over 9 pounds per square foot of surface, the high-water mark in aviation. The angle of incidence used in flight by Leblanc was much higher than that of Weymann—approximately 7 or 8 degrees.

In straightaway flight the speed of Leblanc is said to have been tremendous, but on turns he was forced to go so wide that he lost ground, and eventually the race. Hamel, lacking the expert-

LEGAL NOTICES

PATENTS

If you have an invention which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand Book on Patents is sent free on request. This explains our methods, terms, and co-operation in regard to PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN.

MUNN & COMPANY
361 BROADWAY, NEW YORK
Branch Office, 625 F Street, Washington, D. C.

PATENTS SECURED OR FEE RETURNED
Free report as to Patentability. Illustrated Guide Book, and Whats The Use of Patents. All sorts of Inventions Wanted and Prizes offered for inventions sent free. VICTOR J. EVANS & CO., Washington, D.C.

Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 12 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

DEAFNESS.

THE DEAF HEAR INSTANTLY with the Acoustic ion. For boneless, also for ordinary cases use Acoustic special instruments. You must hear before you purchase. Booklet free. Acoustic Ass'n, 1269 Broadway at St. Jamaica, N Y City. Paris branch, 6 Rue d Hanovre.

PATENTS FOR SALE.

FOR SALE—Patent No. 983411, Soyr Pocket Baseball Game. Professional players. Object metal, rubber or fiber about four inches square. Will sell on royalty basis of one cent each, and a guarantee of $1000 per year payable quarterly. Highest guarantee gets a sure winner. Robert Rossi Pres., Geneva, N.Y., Newport.

ARTIFICIAL RAIN—New system of irrigation combined with electrified water. Heat and obnoxious fertilizer. See illustration on page 170 of this issue. Patented. Capital wanted to exploit same. Patent for sale or royalty. Address Prof. Frank Trobe, K. Box 78 Bk Sta., N. Y. City.

FOR SALE—Entire Patent Right for U. S. of my improved Belt Rack shown in another column of this paper. Has been in every day use for one year and proved to be practical and valuable. Will dispose very low price. Address, Robert L. Smith, Box 688, Lincoln, Nebraska.

WANTED.

LOCAL REPRESENTATIVE WANTED. Splendid income assured right man to act as our representative after learning our business thoroughly by mail. Former experience unnecessary. All we require is honesty, ability, ambition and willingness to learn a lucrative business. No soliciting or canvassing. This is an exceptional opportunity for a man in your section to get into a big paying business without capital and become independent for life. Write at once for full particulars. Address, P. E. Mason, Supt., Long Natural Gas & Oil Operative Real Estate Company, 1, 2, 3, Marden Building, Washington D. C.

WANTED—To communicate with machinery dealers and those interested in the stone industry, also the names and addresses of owners of Stone Quarries in WALLS. Address Quarry Supt. Portlandar, Kashkawar, India.

MISCELLANEOUS.

FREE—"INVESTING FOR PROFIT" Magazine. Send me your name and I will send you four magazines absolutely free. Before you invest a dollar anywhere you should read it. It is worth $5 a year to any man who intends to invest 25 or more per month. Tells you how $1.00 can grow to $50.00—how to judge different classes of investments; the real investment Power of your money. Magazine six months free if you write to-day. H. L. Barber Publisher, 68, 30 W. Jackson Blvd., Chicago, Ill.

MAKE BIG MONEY operating a Daydark Post Card Machine. Photo postal cards made and delivered on the spot in ten minutes. Operates in open air, no dark room necessary—it does not require an experienced photographer to make first class pictures. Pays a gross profit of $20 per cent. Write today for free sample and catalogue. Daydark Specialty Co., Dept V, St. Louis.

MOTORCYCLES CHEAP—Send to-day for free catalog of new and used motorcycles. Also motorcycle accessories and attachments. Agents wanted for motorcycles into motocycles. Shaw Manufacturing Company, Dept. M, Galesburg, Kans.

METAL NOVELTIES MANUFACTURED—Thoroughly equipped for quick service and low prices. Up to date device for manufacturing metal novelties. Reference—Any well rated commercial agency. The Norton Manufacturing Company, Bristol, Conn.

LISTS OF MANUFACTURERS.

COMPLETE LISTS of manufacturers in all lines published in about weeks at moderate rates. Mail and special lists compiled to order at various prices. Figures always subject to quotation in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

INQUIRY COLUMN

Inquiry No. 9368.—Wanted, addresses of parties having raw materials or minerals containing potash in any form.

Inquiry No. 9347.—Wanted, to buy a Parmelee serpent watch.

Inquiry No. 9294.—Wanted, the name and address of manufacturers of Ferris wheels and park novelties, such as are used for painting advertisements on.

Inquiry No. 9329.—Wanted, to buy or a patent roller ball bearing axle, which would be purchased on a royalty basis; it must be clean and fully proved.

Inquiry No. 9330.—Wanted addresses of parties having Philippine records, if able to ship one.

Inquiry No. 9327.—Wanted addresses of firms selling second-hand water turbines.

Inquiry No. 9326.—Wanted addresses of parties having rum stowages to offer in any part of the world.

Inquiry No. 9325.—Wanted to buy a machine for removing the bodies of a fibre.

Inquiry No. 9360.—Wanted addresses of parties able to ship corundum cement. Hard, emery or any material suitable as an abrasive.

mess of Leblanc, came to grief on the first turn, being unable to recover from the inclination because of the inadequacy of his supporting surface. This is a feature for which this type deserves to be severely criticised. It merely points to what an absurd sacrifice M. Blériot went to gain a little in speed.

THE WRIGHT BIPLANE.

This "Baby" type is already familiar to many, and will be recognized as a counterpart of the small machines flown at Belmont Park last year Mr. Ogilvie used an N. E. C. engine rated at 50 H.P. and with it attained a speed only slightly greater than with the 80 H.P. Wright engine used by him last year

The biplane measured 21¼ feet in span, and 3¼ feet in depth The total area was 145 square feet. The aspect ratio was over 6 to 1, and the loading about 6 pounds per square foot

The rudder and control systems are precisely the same as on all the standard Wright types

Mr. Ogilvie introduced an innovation in fixing to the next to last strut near either end of the main biplane cell, single vertical surfaces, to act as keels These doubtless added to the resistance but Mr Ogilvie found that they aided in steering.

The noticeable fact about this machine in flight was the manner in which it appeared to "drag" as compared with its swifter competitors This in a measure was due to its lower power, but more particularly to its very much higher resistance

The main features in which the types differ may be summed up as follows: The Nieuport had a light loading and a very small angle of incidence, which, added to the small resistance of the framing, made the total resistance to be overcome by the propeller thrust very small The Blériot had a high angle of incidence, a frame of considerable resistance, and a very small surface. The power plants being the same, it is evident that the Blériot, with almost only one-third of the surface, offered as great a resistance to motion as did the Nieuport This does not only speak well for the Nieuport but badly for the Blériot

The Wright was lower powered but had a medium loading with a very high framing resistance

COMPARATIVE FEATURES

The sections of the planes of these three types are given M Eiffel in his classic experiments has investigated all these sections. For the Wright, the best ratio of lift to drift is obtained in the neighborhood of 2 or 3 deg.; for the Blériot at 3 deg. and for the Nieuport at 6 deg The normal angle of flight of the low-powered Nieuport is at 6 deg—the most efficient one Any higher power for the same weight, results in higher speed only upon reducing the angle of incidence The speed does not increase proportionally with the horse-power Upon using a 100 H.P. motor—as did Weymann—only a slight increase of speed is attained over a 70 H.P. Since he appeared to be flying at as low an angle as possible the conclusion is at once drawn that for lifting this particular weight of machine a limit has been reached Upon further increasing the motive power, to offset the tendency the machine would have to ascend, it would almost appear necessary to actually add weight to it, to hold it down This merely emphasizes the precise balance that exists in aeroplane design between weight, speed, and power

M Eiffel's investigations show a particularly interesting difference in the aerodynamics of these types On the Wright, he found the distribution of pressure to be very high at the extreme entering edge region of the plane, the pressure decreasing in intensity toward the rear. On the Blériot the total pressure, suction on the upper face and pressure on the under face, was a maximum at one-fifth of the chord from the leading edge, but as on the Wright, decreased sharply toward the rear On the Nieuport, a different situation was found The pressure was a maximum much nearer the center of the plane, sloping easily to the front and the rear, thus indicating a far more uniform intensity and distribution of pressure. This has a great deal to do with explaining the high efficiency of the Nieuport product.

LESSONS OF THE RACE.

What the Wright gained in strength and stability it lost in its inherently higher resistance—at once stamping the biplane as a slow-speed machine

The monoplanes at last proved themselves beyond doubt the ideal type for rapid flying. Two important considerations result from actual observation of the flight of Weymann's Nieuport and Leblanc's Blériot Had Weymann had less surface on the straight stretches he could have attained a much higher average speed, but at the turns in order to "bank" with a proper degree of safety and rapidity he needed every square inch of surface he had On the other hand Leblanc had about as little surface as possible for straightaway flight, but on turns he was forced to go far out of his course and skid to an alarming extent Had Leblanc been provided with more surface at the turns he could have "banked" more sharply and thus greatly increased his average speed. The two facts point unerringly to the immense advantages that would be possessed by a machine with variable surfaces—reduced to a minimum in straight flight, and spread to a maximum in landing, starting, and negotiating sharp turns Never before has the real significance of the variable surface aeroplane been more powerfully suggested—a key to still faster flight.

The important and pronounced characteristics exhibited by the machines in making sharp turns should permanently fix these as one of the characteristic requirements of the contest To further test the machines more difficult maneuvers should be made imperative, such as clearing certain altitudes and turning both to right and left.

In addition to this time should be taken from standstill to standstill thus bringing into the contest the highly important elements of starting and alighting It is not unlikely that the 1912 cup race will see speeds of 90 miles an hour reached and perhaps surpassed

Etching Metals by Electricity

(Continued from page 178)

the fish-glue preparation in the same way as the albumen, draining the excess only partially off the plate Then insert it in a whirler, spin this around at a moderate speed over the flame of a gas stove, about one foot above the flame In the course of about two minutes the plate can be removed from the whirler, stood on end to cool, then placed upon a negative that has been made with a screen of about 100 lines to the inch The pad of cardboard is now placed upon the back of the plate The back board is inserted, and fixed with considerable pressure so as to insure complete contact Now place the frame out in the sunlight An exposure of from two to five minutes will be required Take the printing frame to the dark room, remove the plate under an orange-colored light and pour over it a solution of aniline violet in water A teaspoonful of the dye to a pint of water is about the right amount Drain off the dye and allow a very gentle stream of water to flow over the plate Wipe the surface with a tuft of wetted absorbent cotton; this must be done with great care, and a very light touch The image will now appear in beautiful violet dots all over the plate, which must be allowed to drain and dry, or it may be replaced in the whirler, and dried in the same manner that was used to set the sensitive coating The image must now be burnt in Take the plate, grip it with a pair of flat-nose pliers at one corner hold it over a gas-stove flame, turned down rather low Turn the plate around, keeping this up until the image seems to disappear Continue the heat and motion until the image turns to a medium chestnut brown Remove the plate at this stage, brush the back and edges all over with asphaltum varnish, allow to cool, when it is ready for the etching. This must be carried out in just the same way as for zinc, using a separate bath of salt and acid, while the time for etching will be about the same as for zinc This protective top is called enamel; it will resist the etching liquid perfectly. If the etching is to be made in very fine dots, only two or three minutes is necessary, when the face can be brushed well over in clean water, the asphaltum varnish

The Warner Auto-Meter Is the "Hall-Mark of QUALITY" on an Automobile

PROSPECTIVE buyers and those in doubt decide on the quality of the car from the speed indicator it carries.

Note Why This Is True—

The speed indicator is the most-looked-at thing on a car The driver refers to it constantly every instant the car is in motion. Aside from indicating speed and distance it is used to check up every important operation of the car—to determine the efficiency of tires, how much gasoline per mile is being used, and in many other ways *it audits the car's performance*

Because of its marvelous sensitiveness and accuracy, and its ability to *continuously* give perfect service during the life of *many cars*, the Warner Auto-Meter is the speed indicator used on the choicest and best cars everywhere.

The Warner is so generally used on Quality cars that its presence on an automobile is accepted by the motoring public as evidence that the car itself is good and reliable.

It is an everyday occurrence to hear one motorist say to another "I don't see the name of the car, but it *must be a good one*, for it has a Warner on it"

It is logical that it should be so

Car designs are so uniform that it is difficult to tell one car from another—or the poor from the good by looking at them For the points which make one car better than another are concealed under the hood—or the floor—or are covered with paint and varnish

The Warner Auto-Meter is always in plain sight. Its supreme quality is generally known. It implies the same quality throughout the car.

Of course there are the uncaring in the automobile world as elsewhere Anything that runs is to them a "good automobile" Any speed indicator is "good" if the hand moves The term "sweet running motor" has no meaning to them and "accuracy and exactness" in the speed indicator is a secondary consideration to *price*

We cannot sell—nor do we want to—the man content with inferiority and who puts price before performance.

One part of our trade is drawn from the *car manufacturer* who makes a good, reliable car—and who refuses to be influenced by the fact that "he does not make it and is thereby not responsible," to equip his good car with an inferior and unreliable speed indicator

Such manufacturers either equip with the Warner or insist that their dealers and agents recommend it as of even quality with their car.

The other part of our trade comes from the car buyer who purchases a good car and desires every item of equipment to be in harmony with it **Those who *care*, specify and insist on the**

WARNER AUTO-METER

"The Aristocrat of Speed Indicators"

THE Warner can be secured through reputable Automobile dealers in any city or town in the United States. Warner branches are maintained in all the principal cities for the convenience of these dealers and their customers. Inquiry to Beloit or at our branches is invited for Warner literature.

removed, as in the case of zinc, the plate trimmed and mounted in just the same way upon a wooden block. The current used in this case, generated by the battery described, will be about three or four amperes, and the electromotive force three volts.

Fig 1 of the illustration was etched as described on zinc, and Fig. 2 upon copper

The Current Supplement

WE have had occasion recently to discuss in our columns the extension of docking facilities for the port of New York, rendered imperative by the ever-increasing size of trans-Atlantic liners. This week's issue of our SUPPLEMENT, No. 1859, brings an account of the steps taken at Southampton by our cousins across the sea to face the situation. Our English correspondent writes on the new docks in the course of construction for the White Star Line.—The readers of the SCIENTIFIC AMERICAN are familiar with the Soya bean. This remarkable seed yields a "vegetable milk," from which may be derived, as from animal milk, a cheese and a species of casein. These points and others are dealt with in an article on the "Extended Utilization of Soya Bean Products."—An illustrated account of the methods employed in measuring radio-activity is given by André Conte.—The fourth instalment of Donald Murray's valuable article on Printing Telegraphy appears in this issue.—How much money is lost to railway companies by locomotives held up in the repair shop is the question dealt with in an article entitled "What is a Locomotive's Time Worth."—The dimensions of the M'Adoo tunnel impose certain restrictions upon the cars operated therein. These cars are illustrated and described in a special article.—It is extremely difficult to extinguish fires in such inflammable liquids as kerosene. What can be done by spreading a blanket of foam over the surface of such burning liquid is described in an article from *Prometheus*.—W. A. DuPuy gives an account of Dr. L. W. Austin, Government Expert on Radio-Telegraphy, and his important achievements.—E. F. Harran, of the Calcutta Port Commission, writes on the Indian tea trade.—An illustrated article is devoted to "The Influence of Erosion by Water in Modeling the Landscape."—Some notes on "Underground Water for Public Use" are cited from a recent pamphlet issued by the United States Geological Survey.—Prof. Charles E. Munroe writes on "Our Dependence upon the Nitrate Supply for National Defense."—Prof. Dobereck speaks on the subject of "The Proper Motions of the Fixed Stars."

Cuttlefish Farms

AT several points on the British coasts there are located cuttlefish farms, where the little creatures are kept in tanks or ponds to be "milked" of their ink.

The pond or tank is connected with the sea by a pipe, and a thousand or more cuttles are kept in a single one. They present a curious sight as they move about, trailing their long arms and starting out of their bulging eyes.

They are guarded by screens with a view to preventing fright, for, if they are suddenly scared, they will emit their "milk" in the water, a dead loss to the cuttlefish farmer. The fluid, or milk, is very valuable, and each cuttle will yield about $3.50 worth a year. It is secreted in a bag, which can be opened and closed at will, the cuttle ejecting the fluid to darken the water so that it may escape unseen when attacked.

The best cuttlefish are obtained in China, where for some reason or other, they produce the best quality of "milk."

When the farmer considers it an opportune time to milk the cuttles he proceeds by opening the sluices of the ponds and gently agitating the water. The cuttles then swim around the pond, and as soon as one passes through the sluice is closed. The cuttle passes down a small channel into a basin or metal receptacle, and as soon as it is securely there the water is drained off. It is then frightened, and at once squirts the fluid from the bag. When it is exhausted it is lifted out, the milk is collected, and the basin is prepared for another.

Notes and Queries

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12518) S. R. W. asks: In your Railroad number I note in one of the articles (page 590) that reference is made to the fact that in some instances the train dispatcher is able to communicate with the conductor of the train by telephone. Will you please inform me as to the construction and methods employed in this system? A. Communication was made with moving trains a good many years ago. A system which bears the name of Mr. Edison has been used. It employs the induction of the current to produce a current in the telephone circuit on the car of the train. The main circuit is by the side of the road. The receiving circuit is on one of the cars of the train. The induction of the current in the main circuit is sufficient to generate a current in the circuit on the car, and thus enable one to hear the message. By the same means a message can be sent from the train, and these circuits have been used by passengers to send and receive messages en *route*.

(12519) A. H. M. asks: In regard to query 12470 of June 24th, 1911, issue, I would like to state the following: It is a well-known fact among those who have seen service on submarine vessels, that it is possible to balance a submarine boat at any desired depth. The greater the depth at which it is desired to balance the boat, then the greater the amount of negative buoyancy (in the form of water ballast) which must be carried. From this it would be inferred that the density of sea water is not quite a ratio to the depth of the water, and I am of the opinion that lack of circulation as the depth increases naturally results in greater concentration and density. Theory leads us to believe that an object that is heavy enough to sink will continue to sink to the bottom, but the fact that water is not throughout a medium of uniform density is often not considered. A fine compressibility of water is about 1/22000 part per atmosphere, and an increase of one atmosphere is had at about 33 feet below the surface of the sea. From this statement it is not difficult to calculate the number of pounds of water ballast required by a submarine of known volume and weight to balance the increase of buoyancy due to depth. This is, however, not the question in the query referred to. The fact is that if a heavy body sinks in water, it will continue to sink till it reaches the bottom if its weight is not changed. This the submarine would do if its weight was not changed by changing the quantity of water in it. The difference in density due to the quantity of salts dissolved in the water is not great at different places and does not affect the result to any great extent. The continuous sinking of a body in the sea is due to the fact that it is compressed more and made denser by its deeper submersion than the sea water is at the same depth. The submarine is not compressed in sinking to ordinary depths, but its volume and weight are changed by admitting water to make it sink and removing water to make it rise.

(12520) R. E. T. says. My house is frame with slate roof. I use electric light 115-volt, 60-cycle two-wire system, with the wires entering at the top of house. The wiring was put in some years ago. Would it be better to throw the main switch during an electrical storm or not? One side of the transformer is grounded, and I have combination gas and electric fixtures. A. If you have not a good lightning arrester at the point where the electric wires enter your building, you would better have one put on without delay. Even after this is done, the house is better protected from lightning if the main switch is open during a thunder storm. In some places the switch at the generating station is opened during a thunder storm and all lights are cut off.

(12521) E. P. says. I am experimenting with electricity, and use a lot of dry cell batteries in my work, and I find it very expensive to buy new batteries. Won't you kindly tell me a way by which I can restore my old batteries again? A. We regret to have to say that there is no way of fully restoring old dry cells. They are generally thrown away when exhausted. Some have punched holes in the zinc cases, and put the whole in a glass jar with a solution of ammonium chloride. They will then give some more service, but not enough so that the operation is profitable. Some have dug out the top and soaked the cell in the ammonium chloride solution. This is the better way. If time and labor are of little value, one can perhaps profitably work on old dry cells; otherwise, not.

Handy Man's Workshop and Laboratory
Compiled and edited by A. RUSSELL BOND. 12mo., 467 pages, 570 illustrations. Price, $2.00.
¶ This is a compilation of hundreds of valuable suggestions and numerous ideas for the mechanic and those mechanically inclined, and tells how all kinds of things can be done, home-made tools and appliances. The suggestions are practical, and the solutions to which they refer are of frequent occurrence. It may be regarded as the best collection of ideas of resourceful men published, and appeals to all those who find use for tools either in the home or workshop. The book is fully illustrated, in many cases with working drawings, which show clearly how the work is done.

Concrete Pottery and Garden Furniture
By RALPH C. DAVISON. 16mo., 196 pages, 140 illustrations. Price, $1.50.
¶ This book describes in detail in a most practical manner the various methods of casting concrete for ornamental and useful purposes. It tells how to make all kinds of concrete vases, ornamental flower pots, statuary, concrete benches, concrete fences, etc. Full practical instructions are given for constructing and making the different kinds of molds, making the wire forms or frames, selecting and mixing the ingredients, covering the wire frame, modeling the cement mortar into form, and casting and finishing the various pieces. With the information given in this book, any handy man or novice can make many useful and ornamental objects for the adornment of the home or garden. The information, as color work alone is worth many times the cost of the book.

Any of these books will be sent, postpaid, on receipt of advertised price

Aeronautic Notes

Current Aviation Meets.—The first big aviation meet of the present year in the Middle West opened on the 12th inst. in Chicago. Over twoscore aeroplanes of different types, piloted by the leading American aviators, were entered, and $80,000 in prize money was competed for. The meet was held at Grant Park on the shore of Lake Michigan, which, though a windy spot, did not affect the flights materially. The first big meet of the year in the East opens at Boston on the 26th, while a second Western meet will be held at St. Louis, beginning September 30th.

Big Prizes for Cross-country Flights.—The offer of $10,000 to Harry Atwood for a 1,000-mile cross-country flight, which is said to have been made recently by a prominent patent attorney of Washington, has caused this daring aviator to attempt a flight from either Milwaukee or St. Louis to New York in the near future. A prize of a like amount has been offered by Gen. Charles M. Taylor, the proprietor of the Boston *Globe*, for a 150-mile interstate monoplane circuit race during the Boston meet. This is the second $10,000 prize donated by General Taylor, as he gave a similar amount a year ago for a flight from the aviation field at Squantum to the Boston Light and return. This prize was won by Grahame-White with his Blériot monoplane. A prize of $7,500 has also been put up for biplanes to race over the same course on September 2nd. The cities included in the circuit are Nashua, N. H., Worcester, Mass., and Providence, R. I. The $10,000 will be divided into three prizes of $7,500, $1,500 and $1,000, respectively, while in the biplane race the prizes will be $5,000, $1,500 and $1,000.

The First Inter-city Aeroplane Race.—The first aeroplane race across country from New York to Philadelphia was flown on Saturday, August 5th, when Messrs. Beachy, Ely, and Robinson of the Curtiss force started from Governors Island, flew up the Hudson to Thirty-third Street, circled over the roof of the Gimbel building, and headed for Philadelphia. Beachy, who has already made a name for himself by his flight over Niagara Falls a short time ago, won the race, his time from store to store for the 90 miles being ¾ minute less than two hours, including a stop at Trenton, in order to take on fuel. Robinson was second in two hours and one-half, while Ely only got as far as Princeton Junction. Just before reaching Philadelphia Beachy passed into a shower and was thoroughly soaked ere he circled above the Gimbel building in Philadelphia, saluted the statue of William Penn on top of the City Hall, and landed in Fairmount Park. Notwithstanding this fact, he gave a fine exhibition flight while waiting for his brother aviator. All three aviators used Curtiss 50 horse-power biplanes having Keyllnder V-type motors. The prize was $5,000 in cash. It was put up by the Gimbel firm with an idea of encouraging cross-country inter-city aeroplane racing.

A New Distance Record for the Michelin Trophy.—M. Vedrines, the winner of the Paris-Madrid race, made a trial for the Michelin trophy on the 9th inst. in France, and succeeded in covering 800 kilometers (497.09 miles) in 7 hours, 58 minutes, and 36 seconds. This corresponds to an average speed of 62¼ miles an hour, which is excellent for a sustained flight over a closed circuit. This new record supplants that made by M. Loridan of 469 miles in 11¾ hours on the 21st ult. The new record was made with a Morane monoplane instead of with a Farman biplane which was used by M. Loridan. In competing for the trophy this year the flight must be made across country, back and forth between two points from 50 to 100 kilometers apart. Competitors may descend as often as they please to take on fuel or make repairs, but no part of the machine can be replaced that is sealed by the officials. An average speed of 50 kilometers (31 miles) an hour must be maintained. The winner of the trophy this year will be the pilot who, before November 1st, has covered the greatest distance over a closed circuit. This distance must exceed the 552.935 kilometers (552.21 miles) scored by M. Tabuteau last year.

Fire Fighting and Telephoning

Both Need Team Work, Modern Tools and an Ever Ready Plant, Everywhere

Twenty men with twenty buckets can put out a small fire if each man works by himself.

If twenty men form a line and pass the buckets from hand to hand, they can put out a larger fire. But the same twenty men on the brakes of a "hand tub" can force a continuous stream of water through a pipe so fast that the bucket brigade seems futile by comparison.

The modern firefighter has gone away beyond the "hand tub." Mechanics build a steam fire engine, miners dig coal to feed it, workmen build reservoirs and lay pipes so that each nozzleman and engineer is worth a score of the old-fashioned firefighters.

The big tasks of today require not only team work but also modern tools and a vast system of supply and distribution.

The Bell telephone system is an example of co-operation between 75,000 stockholders, 120,000 employees and six million subscribers.

But to team work is added an up-to-date plant. Years of time and hundreds of millions of money have been put into the tools of the trade; into the building of a nation-wide network of lines; into the training of men and the working out of methods. The result is the Bell System of today—a union of men, money and machinery, to provide universal telephone service for ninety million people.

The Scientific American Cyclopedia of Formulas

The Most Complete and Authoritative Book of Receipts Published

Partly Based on the Twenty-Eighth Edition of
"The Scientific American Cyclopedia of Receipts, Notes and Queries"

Edited by ALBERT A. HOPKINS, Query Editor of the Scientific American

THIS is practically a ***new book*** and has called for the work of a corps of specialists for more than two years. Over 15,000 of the most useful formulas and processes, carefully selected from a collection of nearly 150,000, are contained in this most valuable volume, nearly every branch of the useful arts being represented. Never before has such a large collection of really valuable formulas, useful to everyone, been offered to the public. The formulas are classified and arranged into chapters containing related subjects, while a complete index, made by professional librarians, renders it easy to find any formula desired.

"As Indispensable as a Dictionary and More Useful"

Following is a List of the Chapters: I Accidents and Emergencies. II. Agriculture. III Alloys and Amalgams. IV. Art and Artists' Materials. V. Beverages; Non-Alcoholic and Alcoholic. VI Cleansing, Bleaching, Renovating and Protecting. VII. Cements, Glues, Pastes and Mucilages. VIII. Coloring of Metals, Bronzing, etc. IX. Dyeing. X. Electrometallurgy and Coating of Metals. XI Glass. XII. Heat Treatment of Metals. XIII. Household Formulas. XIV. Ice Cream and Confectionery. XV. Insecticides, Extermination of Vermin. XVI Lapidary Art, Bone, Ivory, etc. XVII Leather. XVIII Lubricants. XIX. Paints, Varnishes, etc. XX Photography. XXI Preserving, Canning, Pickling, etc. XXII Rubber, Gutta-Percha and Celluloid. XXIII. Soaps and Candles. XXIV Soldering. XXV Toilet Preparations, including Perfumery. XXVI Waterproofing and Fireproofing. XXVII Writing Material. Send for detailed illustrated prospectus.

MONOPLANES and BIPLANES

THEIR DESIGN, CONSTRUCTION & OPERATION

The Application of Aerodynamic Theory, with a Complete Description and Comparison of the Notable Types

By GROVER CLEVELAND LOENING. B.Sc., A.M., C.E.

CRITICISM

"The first treatise upon aviation which we have seen which may be styled really complete. . . . . Actual aeroplane designing is the central theme of the volume. . . . . The prominent types are exhaustively compared. . . . . The illustrations are a notable feature."
—*Rochester, N. Y., Chronicle.*

A very complete account of the theory of heavier than air flying machines with a technical description of nearly all the present types of aeroplanes. . . . Presents in compact shape the substance of aerodynamic theory . . . . Easily comprehensible to the reader who can concentrate his attention. . . . It is the most scientific popular book on the aeroplane that we have come across so far."
—*New York Sun*

"Many writers have failed to realize the demand which exists for aero literature in which mathematical deductions are a necessary but not predominant part of a comprehensive exposition of the entire subject. For a writer to steer a straight course between the mazes of trigonometry on the one hand, and the superficialities of mere discussion in a popular vein on the other is to accomplish what can be done only by one who is himself a thorough student in the finer details, but who can sufficiently divorce himself from the mathematical atmosphere as to present the whole subject from a broad standpoint, making it readily intelligible and informative to the less erudite seeker after knowledge."
—*Phila. Inquirer*

"Students learned in aerodynamics and laymen ordinarily interested in aviation will find equal delight in reading 'Monoplanes and Biplanes.' The book is a welcome addition to the libraries of those who have realized the future of aerial navigation, and desire a work treating solely of the heavier than air machines written by an acknowledged expert and with no hobbies hidden in the discussion."
—*Boston Journal.*

"While enthusiastic in his interest he becomes one who has written so superb a volume, Mr. Loening is also rigidly accurate as the most exacting scientist could demand. Here is a work which is at once a history and textbook which may be depended upon for everything that is within the range of actual knowledge. To say that 'Monoplanes and Biplanes' is at once new and authoritative with reference to the entire subject and that it is practical in the highest degree is the just praise due to this volume."—*Buffalo News.*

"Mr. Loening has written, in fact, for the man who wishes to apply practically the experience that has already been gained."
—*New York Times.*

MARK TWAIN'S WORKS at 1/2 the Former Price

25 VOLUMES

The humor, the philosophy, the humanity, the gentle kindness of Mark Twain counteract the strain of our intense American life.

Every American Needs His Mark Twain

Because—
His great books afford the relaxation which is absolutely necessary for every busy man and woman.

Because—
They make one realize the joy of living.

Because—
They keep a keen edge on one's faculties.

Because—
These 25 volumes include the best travel books published, with most entertaining descriptions of places of interest all over the world,

Because—
They are wonderful character builders; they stand for straightforwardness, honesty and sincerity.

Because—
They enable one to make Mark Twain's intimate knowledge of human nature and knowledge of life part of one's mental equipment—for all time.

Because—
They afford the best way—short of years of experience—to learn these things which are real. One may benefit by the author's rich experience—use his powers of observation—learn human nature through his pages.

Because—
The reading of his books will give one more genuine pleasure, and more real, intellectual enjoyment than anything else money can buy.

Because—
The new Author's National Edition of his works makes it possible for you now to secure

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are striking, the articles short, and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately and in simple terms, the world's progress in scientific knowledge and industrial achievement. It seeks to present this information in a form so readable and readily understood, as to set forth and emphasize the inherent charm and fascination of science

Aeroplane Touring vs. Exhibition Flying

LAST week the followers of aviation in this country were given an opportunity to contrast the aeroplane as a practical means of transport across country with the aeroplane as a provider of sensational amusement.

No more striking demonstration of the utility of the aeroplane for pleasant and rapid touring could have been given than Atwood's flight, at an average speed of between forty and fifty miles an hour for the first half of his journey from St. Louis to Chicago and New York, a distance of about 1,265 miles, or double that covered by him in his memorable flight from Boston to New York, Atlantic City, and Washington some weeks ago.

On the other hand, the dangers of exhibition flying on the edge of, and over, a large body of water were distressingly brought out by the deaths from bad falls of two promising young men, both of whom, had they lived, would in all probability have contributed to the progress of aviation in America.

These two fatal accidents seem to have been caused in much the same way, i. e., as the result of a sudden descent at a sharp angle with power on, ending in a quick leveling of the machine before it struck the ground or water. The terrific strain imposed upon the planes and guys, amounting to many times that caused by normal flight (as explained by Dr. Zahm in an article on another page), caused the guys to give way, and the wings or planes to collapse, after which the aeroplane fell precipitately to the ground or the water of the lake.

The first machine that collapsed in this way was a Baldwin biplane driven by William Badger, a wealthy young amateur aviator of Pittsburg. The planes crumpled up and the aeroplane fell into a pit. As is usual in an accident of this sort with a biplane, the motor, which is mounted directly behind the man, fell upon the aviator, fracturing his skull and badly mutilating his body. He died within three-quarters of an hour.

The second fatality, which occurred only a short time after the first one, happened to St. Croix Johnstone, the leading pilot of the Moisant monoplane and the holder of the American endurance record of over four hours in the air. Johnstone had been flying for two and a half hours, most of the time over the lake, when he made a sharp descent from a height of some 1,500 feet. Suddenly, when less than 500 feet above the surface of Lake Michigan, the aviator lost control and the machine plunged into the water. Johnstone was unable to save himself in the way that Arthur Stone did under similar circumstances two days later, namely, by diving from the machine just before it struck, and he was carried below the surface and drowned. Robinson in a Curtiss hydro-biplane was flying nearby at the time. He alighted upon the water and tried to render assistance, but was unable alone to extricate his fellow flyer.

While the two fatal accidents were not due to the wind, this had much to do with several of the other disasters. The Windy City made good its name by producing exceedingly strong breezes for the flyers to battle with. One of the most peculiar accidents happened on the second day, when McCurdy's biplane is said to have caught fire from contact with some high-tension electric light wires. The machine was entirely consumed. The third day of the meet Simon, in a Blériot monoplane, and Hammond, in a Baldwin biplane, each fell into Lake Michigan. The latter dived from his machine before it struck the water, while the French aviator remained in his monoplane until he was rescued.

In making his long-distance tour Harry Atwood has shown the aeroplane, when favored with good weather, to be fully as dependable as the automobile. Besides this it is a speedier, cleanlier, and more pleasurable means of transport. The $10,000 prize Atwood expects to win, in addition to the various sums paid him for flying over towns and alighting, has made his remuneration from his ten days' outing several times greater than that of the best aviator at the Chicago meet. In addition to this, his flight has given many more people, gratis, their first view of an aeroplane.

We are glad to note that at the Boston meet, which opens to-day, there will be two cross-country circuit races for monoplanes and biplanes respectively, for prize money aggregating $17,500. Generosity of this sort by the newspapers of the country will do more to introduce the aeroplane as a practical machine than hundreds of aviation meets, ending in death and financial failure.

Artificial Frogs

A CABLE dispatch from Paris last week brought the startling news that Prof. Bataillon, the well-known biologist, has succeeded in producing "artificial frogs." Announcements such as this have become so frequent of late that they have almost ceased to startle the *blase* newspaper-reader; but whether one is startled or not, the announcements are essentially false and misleading. We are in fact no nearer the creation of "artificial frogs" or "artificial life" in any form, so far as actual control of the conditions that lead to the origin of living matter is concerned, than we were a dozen years ago.

The problems involved in the work which leads to these sensational announcements are of two entirely different kinds. In the first place we have the question of the physical and chemical processes that go on in the living protoplasm, with the attempt to reproduce as far as possible a combination of molecules that will behave in some respects as does the living matter of a cell. If we could succeed in bringing together from the bottles in the laboratory a combination of substances that would react upon one another and upon the environment as does the mass of substances we call an "Amoeba" we should have succeeded in creating "artificial life." Many attempts have no doubt been made to create life in this sense. And many attempts—from those of Butschli to those of Leduc—have succeeded so far that they have reproduced some of the peculiarities of living things in non-living matter. But Prof. Bataillon did not try to do anything like this. His problem was an entirely different kind.

He was concerned chiefly with the question, "How does the sperm cause the egg to develop?" In attempting to reduce the influence of the sperm upon the egg to physical and chemical terms, the biologist may be said to deal with the creation of life, but the use of these terms in that sense is purely metaphorical. At any rate, this is the nature of the general problem with which Prof. Bataillon is concerned, and his results are the logical successors of earlier experiments along the same line. Starting with Prof. Jacques Loeb's experiments, in which the unfertilized eggs of sea-urchins were induced to develop by the action of physical forces (osmotic pressure) and by various chemicals, passing to Loeb's later experiments in which the chemical action was analysed further into its electrical factors, and from these to the experiments of Delage, who induced fertilization by means of electric charges, we have a continuous series of contributions to the solution of this problem. But from Delage's "artificial parthenogenesis" by means of electrical charges through the surrounding medium, to Bataillon's artificial parthenogenesis by means of chemical charges through the unfertilized egg itself, is only a step—but an important step.

In all of these experiments the biologist has before him well-defined problems; in none of them does the experimenter for a moment think that he is making "artificial life." For if we could succeed in making all frog's eggs or sea-urchin eggs develop into adults without fertilization, we should not be creating life at all; we should simply cause eggs to develop under artificial conditions. To create life we should have to provide the egg artificially, as well as the stimulus for its development.

Nevertheless these experiments are of importance, as well as of interest, for they lead not only to a better *understanding* of the fundamental processes, but also, eventually, to a surer *control* of vital processes, in animals and in plants. Without any illusions as to the likelihood of artificial frogs being sent here from France next year, or even the year after, we may still find it worth while to learn what has actually been accomplished in these two lines of research. We shall accordingly present to our readers shortly an account of the experiments made to reproduce the physical and chemical peculiarities of living matter, and those made to replace the vital action of one factor in reproduction (the sperm) by chemical and physical processes.

The Abandoned Mill and the Farmer

SCATTERED broadcast throughout our land are hundreds of water mills, long since abandoned. Relics of busy centers these, where the grind of the millstones, the clatter of machinery, and the creaking of the old water-wheel, once vied with the roar of the industrious stream. Now all is still, within the old mill walls, and the dust, the moss, the rot, and the rust, show that it has long since given up its struggle with the progress of modern industry. Wheat is now ground in steam-driven mills, a hundred fold greater, and little manufacturing plants have moved to the city, where they can avail themselves of steam and electric power close to the consumer of their products. But back in the country the idle mill stream still pours over the old dam, and dashes down the spillway in utter abandon—hundreds, may be thousands of horse-power literally going to waste—while in the adjacent fields the farmer, whom it once served, still toils at his plough and sends his grain a thousand miles away to the steam mill.

Is this really progress? Can we feel justly proud of the industrial advancement of our great nation, while such prodigality exists? But what can be done with these water-powers? A few of them, the larger ones of course, which are advantageously situated, have been set to work generating electricity for light and power purposes. But the smaller ones—have they no further value? Of course they have; and we need not look far afield to find a ready market for this power, small though it may be. Side by side with these idle streams, are the over-driven farmers, whose labor troubles have multiplied appallingly, and who are crying for help to do the necessary work on their farms. Why should such an anomalous condition continue any longer? Why not convert these old mills into electric power stations, and let electricity lighten the farmer's tasks? The first objection that comes to one's mind is that the cost would be prohibitive. That this is not so is clearly proven by the article on another page. Mr. T. Commerford Martin and Mr. Putnam A. Bates, both engineers of highest standing, outline a policy by which these fast-decaying relics may be put to some use. The capital required is not large, and a dozen farmers could band together and install a co-operative electric-generating plant in the old mill, which would furnish all the electricity they would need. The average farmer would not require more than fifty horse-power, and with a co-operative plant he could obtain his power so cheaply as to make it well worth his while. We know of no better way of utilizing the smaller streams of our country, and it does not require a prophet to see in such a plan a material advancement of the farmer's condition. The first co-operative farmers' power generating station will mark a notable step in our industrial progress, and in the conservation of our natural resources.

Another Misplaced Moon

THE long list of blunders committed by distinguished literary men in writing about the moon has received a recent addition, attention to which is called in *L'Astronomie*. A work by M. Maurice Donnay, of the French Academy, contains the following passage:

"We watched the setting of the sun. It seemed as if, in the west, metals were entering into fusion, then cooling rapidly until they assumed a uniform orange tint, while *on the opposite side*, in a sky of pale and, as it were, washed-out blue, a *slender crescent moon* appeared."

Apparently there is need of more intimate intercourse between two branches of the Institut de France; viz., the Academie Francais and the Academie des Sciences. One wonders what must be M. Donnay's outlook, in general, upon the physical universe, if he has never grasped the simple relation between the moon's phases and her position with respect to the sun.

We hope that no reader of this journal needs to be told that the only kind of moon ever seen in the eastern sky near the time of sunset is one that is at or near the full.

The United States Referee Board

How It Came to be Appointed

By Ira Remsen

IN January, 1908, the writer received a letter from President Roosevelt, the essential part of which follows:

"We have reached a point in the enforcement of the Pure Food and Drugs Act where it has become necessary that some scientific questions shall be settled. For this purpose, I have decided that we shall have a Referee Board, of five members, eminent medical men or physiological chemists. The Secretary of Agriculture will certify to this Board each question upon which he desires a final determination. Only those questions will be referred to the Board concerning which there exists a serious difference of opinion among eminent authorities. . . . The Board will have full authority to make all experiments necessary to reach a decision upon the questions submitted. A secretary of the Board and other clerical help will be provided, and the expenses incident to the investigations will be paid.

"It is my desire to secure men of such high character and attainments that when the Referee Board speaks, it will be the final word on the subject so far as the United States is concerned. The questions now pressing for solution, which will probably be referred to the Board immediately, are, whether sulphur dioxide and benzoate of soda are harmful in foods. The Board will enjoy the greatest independence. The government will certify the questions and the Board will work out the answers in its own way, free from hampering influence of any kind.

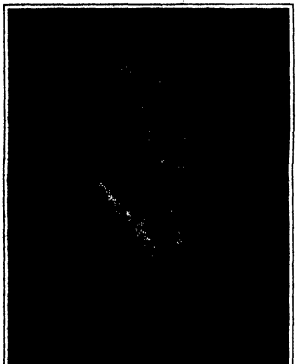
"Perhaps you know one or two men who are available. If so, I ask that you will write me fully about them; also that you will ascertain if their services may be secured, all, of course, in a confidential and tentative way. Prompt action is necessary in this matter, as the Board will be appointed within a very short time."

Having taken counsel with my colleague, Dr. William H. Welch, I wrote the President, January 17th, making some suggestions. On the 21st the President wrote me as follows:

"Won't you accept the presidency or chairmanship of that committee of five? You are the very man I would most like to have on it.

"If you will accept I will later get you to come over to see me so that I may have the chance of talking the matter over at some length with you."

On the 23rd I answered thus:



"I have given careful consideration to your suggestion and am now prepared to say that if after a conference with you, the matter should present itself to me as it now does, and I should find it possible to give the necessary time to the work, I should be strongly inclined to accept your offer.

"If you will appoint a time for an interview, I shall be glad to call on you and talk the subject over."

On the 27th I went to the White House and had a very satisfactory talk with the President. He urged me to accept the chairmanship he had offered and added, "I want you to start this work and get it under way. If you should find it too great a burden you can, of course, withdraw later." Everything he said showed clearly that the only object he had in view was to find out what the truth is as far as this might be possible. The talk between us was on the highest possible plane—refreshingly so. I accepted, and then at the President's suggestion I called on Secretary Wilson, as everything pertaining to the Pure Food and Drugs Act falls within the jurisdiction of the Department of Agriculture. My talk with the Secretary was as satisfactory as that with the President. It was clear that the Board was to be absolutely free from all external influence, that it was to work in its own way, to be, in fact, as free as the air. And let me say here, now that the Board has been in existence for over three years and has had a somewhat stormy time, that President Roosevelt and President Taft as well as Secretary Wilson have allowed us to work without the slightest interference. Our relations have, naturally, been closest with the Secretary and, as chairman, my relations with the Secretary have been particularly close, and it is a great pleasure to me to testify to his uniform courtesy and to the fine attitude he has taken toward our work from the beginning of our service to the present. Nothing could have been finer.

Now, absent the appointment of the other members of the Board. The President turned over to me all the papers in his possession bearing on this subject, and then it appeared that he had written to four or five other university presidents a letter similar to the one quoted at the beginning of this article and that these gentlemen had made some recommendations. The President said to me, "You need not be influenced by these suggestions. Select the men you think best and I will see that they are appointed." After another conference with Dr. Welch I told the President that I should like to have appointed Dr. R. H. Chittenden, director of the Sheffield Scientific School of Yale University, and professor of physiological chemistry therein; Dr. J. H. Long, professor of chemistry in the medical school of Northwestern University, Dr. C. A. Herter, professor of pharmacology and therapeutics in the College of Physicians and Surgeons (Columbia University), New York, and Dr. A. E. Taylor, professor of pathology in the University of California. The appointments were made by Secretary Wilson.

It is superfluous for me to praise these gentlemen or to say a word in defense of their character or scientific reputation. No one at all familiar with the kind of work the Board is called upon to do would venture to call in question the fitness of these members. I may perhaps be permitted to say in regard to myself that I have not engaged directly in the experimental work upon which our conclusions have been based. I have acted as chairman and exercised a general supervision. Having studied medicine before I studied chemistry, and having always been

President of Johns Hopkins University and Chairman of the United States Referee Board.

interested in the problems of physiological chemistry and pharmacology, I think I am not entirely unfitted for the work I have been called upon to do for the government. I have repeatedly suggested to my colleagues on the Board that in my opinion it would be best for me to resign, but they have persuaded me against my will not to do so. While I have become much interested in the work and am convinced that it is of value to the country, I should be glad to be relieved of the burden. In this connection, let me testify to the disinterestedness of the services of my colleagues. They have given much time to the work—in some cases without interruption from one end of the year to the other—and the compensation has been much less than would have been paid these same men for the same service. In all the discussions between the members there has never been any other desire expressed than to learn the truth and nothing but the truth. I do not see how the work could have been done more honestly.

Last winter the Board lost one of its most valuable members by death. Dr. Herter, who had for some time been in poor health, finally succumbed. To the last he kept up his interest and took part in our conferences. Weighing my words, I have no hesitation in saying that I have never known a man of higher ideals. Scientific truth was almost an obsession with him. No one could have associated with him and worked with him without being the better for it.

Another member of the Board has undermined his health by too close application to the work and, though he is on the road to recovery and we have good reason to believe that he will soon be himself again, his example is a warning to the other members.

The vacancy caused by the death of Dr. Herter has been filled by the appointment of Dr. Theobald Smith, professor of comparative pathology in Harvard University, and director of the pathological laboratory of the Massachusetts State Board of Health. Dr. Smith is a member of the board of directors of the Rockefeller Institute for Medical Research, New York, of which Board Dr. Herter was also a director. It should be said that Dr. Smith was deliberately selected by the Referee Board as the best man to fill the vacancy, and that President Taft and Secretary Wilson at once agreed.

Having thus shown how the Referee Board came into existence and under what conditions it has worked and is working, but little more is called for. The Secretary of Agriculture "certifies" the questions to the board upon which he wants an opinion. It is then the duty of the Board to answer the questions to the best of its knowledge and ability, making whatever studies may be necessary for this purpose. It has nothing whatever to do with the decisions of the Department of Agriculture and is in no wise responsible for these decisions. The department makes use as it sees fit of the reports furnished by the Board.

Finally, a few words with regard to the treatment the Board has received. Attempts have been made to discredit it in the eyes of the public. Violent attacks have been made upon it. The members have been accused of a great variety of sins of omission and commission. The law has been invoked to break the force of some of the results obtained. In general there has been much gnashing of teeth. But the Board has not been disturbed by these performances, and as long as it may continue to labor, it cannot allow itself to be disturbed by such irrelevant matters. It is important for the world that such problems as are presented to the Board should be solved and the only way they can be solved is by patient scientific investigation carried on with the sole object of discovering the truth. Scientific questions cannot be answered by the erratic acts of hysterical persons nor by political maneuvering.

Increase of Lung Capacity by Exercise

ACCORDING to careful tests made in a gymnasium in Bonn the capacity of the lungs was increased by regular exercise from 3,388 cubic centimeters or 207 cubic inches to 3,802 cubic centimeters or 232 cubic inches, an increase of 12.14 per cent. In Stuttgart the average increase was found to be from 3,833 cubic centimeters or 233 cubic inches to 4,290 cubic centimeters or 262 cubic inches, being 11.49 per cent. Among the members of the Berliner Ruder Verein (Berlin Rowing Club) the increase for the heavy crew was from 5,600 cubic centimeters or 342 cubic inches to 5,775 cubic centimeters or 352 cubic inches (3.12 per cent.), for the light crew from 4,700 cubic centimeters or 287 cubic inches to 4,875 cubic centimeters or 297 cubic inches, being at the rate of 3.72 per cent.

The Queer Argan Tree

AMONG the most remarkable trees of the world is the argan, which abounds in Southern Morocco, but is seldom seen elsewhere. A "forest" of argans has a curious scattered appearance, because the trees grow singly and far apart. They are very hairy but seldom exceed twenty feet in height. The branches put out horizontally, and begin a yard above the ground. Sheep, cattle and camels feed on the leaves, and goats will stand on their hind legs to reach them, but horses and mules refuse to touch them. The wood is very hard, and extremely useful to the natives, who make charcoal from it. The fruit resembling a large olive, is used to feed cattle and to manufacture a valuable oil. It also furnishes the principal sustenance of many of the poorer natives.

Convert Abandoned Mills into Electric Power Plants

Electricity on the Farm Made Possible by Co-operation

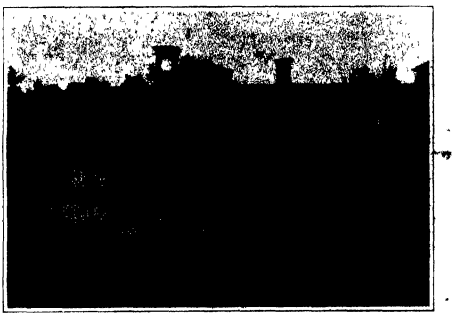
By T. Commerford Martin and Putnam A. Bates

IT is not a unique situation that is pictured in the accompanying photographs. A water power once in active use for mill purposes, is now abandoned because the business has moved to a city offering closer markets and better facilities for obtaining mill workers, while the farmers in the immediate vicinity, who would benefit immeasurably by the utilization of this energy were it transformed into electricity and delivered direct to their farms, allow it to run to waste. If this is the way opportunities are neglected is it any wonder that the country youth leaves for the city where life is more progressive and agreeable? The solution of the rural labor problem lies in making the farm an industrial establishment where head work as well as hand work will be in demand, where the help will find pleasure in their employment because of improved conditions that are at least as healthy and agreeable as can be found in the cities.

With a natural power at hand, such as these photographs show, a co-operative electric plant may be organized and sufficient energy developed to light the buildings and supply the power for a dozen farms. The methods by which this may be done have been known so long as to insure their practicability.

Almost all farmers could use electricity to advantage, were a satisfactory supply available, but few would have sufficient demand to justify its introduction for their particular cases *alone*. Unfortunately many men are farming without any spare resources and of them, no immediate improvements must be expected. This class seems larger than it is in reality, for the American farmer too often cares little for appearance, which accounts for the popular idea that farming must be all work and no play. There is, however, a distinct class of men in any farming section, as in the cities, who look kindly upon co-operative effort for general betterment. These are the men we must depend upon to organize our farmers' water-power electric station.

Located, as this old mill property is in the center of a farming section having a tillable soil of average fertility and surrounded with farms averaging from 300 to 500 acres each on which stock raising, dairying or grain farming is carried on we have as interesting an opportunity to practise "conservation of natural resources" as one could picture.



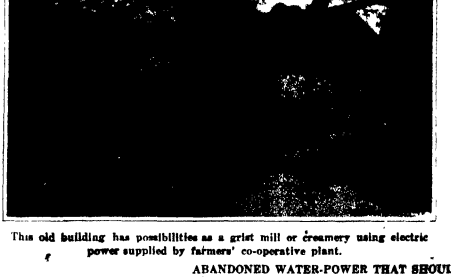
Each farmer can advantageously use some power in and about the barns, and the more electrical power he can use, the less animal or man power will be required. Besides this, electricity will be needed for lighting, a subject much neglected on the farm.

Probably an average of 25 to 50 horse-power of electrical energy could be used regularly on each of these farms, making say an aggregate of 600 horse-power in all, a plant capacity which many rural town central stations would be pleased to possess.

Why, therefore, should not farmers get together and equip this mill as a central station power plant of their own? The property has been abandoned and could be bought for very little. Some would answer this by saying that "such matters are hard to arrange amicably, and the distances of transmission introduce difficulties."

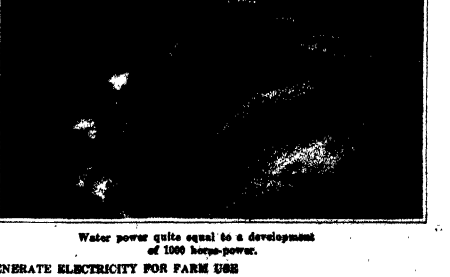
Part of dam and spillway. Very little expense would put this in shape for power service.

Old water power mill, twenty years idle. Would serve as farmers' co-operative electric power plant.



Such things are a matter of organizing only and the distance to which electric power can be transmitted is but a question of economy. The principal elements limiting this are two: the cost of power at the generating station, and the price which can be obtained for the delivered power. The difference between these two elements must cover the cost of transmission, the interest on the investment and the profit. The cost of transmission comprises the loss of power in transmission, the cost of operating, the cost of maintenance and repair. The value of the sum total of the interest, which must be paid upon the investment, and the minimum profit which is considered satisfactory, will have much weight in determining the limiting distance of transmission. A low interest rate and a low rate of profit will, therefore, be conducive to long transmission, both of which factors would naturally be low in the case of a co-operative plant. Hence, it is reasonable to conclude that with a suitably selected system of distribution the transmission question would not introduce great difficulties.

The water power here illustrated would prove quite equal to a development of 1,000 horse-power constant minimum supply, which would be an abundance for our purpose. Within a radius of ten miles, this plant as a center, a rich and only partially developed farming country lies on all sides. To reach the most extreme point of this area, therefore, with electric service and without excessive transmission loss, suggests an economical initial potential of from 6,000 to 10,000 volts.



The questions of transmission and distribution line, right of way and construction are matters that should be carefully worked out and we will not attempt here to discuss these in detail, except to say that better examples are found in our western practice or in foreign countries than in the construction so carelessly erected by many eastern electric service companies, which, fortunately, is now gradually being replaced.

Where electric current is to be carried on overhead

(Continued on page 196.)

This old building has possibilities as a grist mill or creamery using electric power supplied by farmers' co-operative plant.

Water power quite equal to a development of 1000 horse-power.

ABANDONED WATER-POWER THAT SHOULD GENERATE ELECTRICITY FOR FARM USE

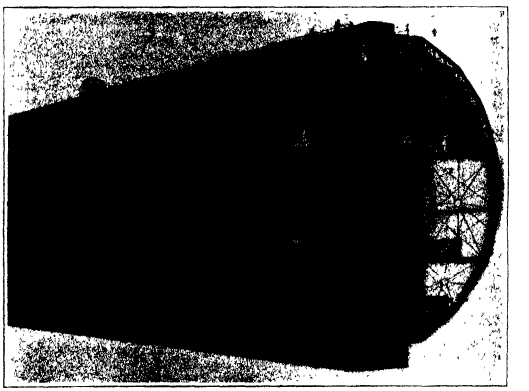
A Study of the Giant Airship of the Future

Its Probable Lines of Development

By Carl Dienstbach

THE very word *airship* implies a craft that will plow the air, much as a large ship plows the sea. From the beginning, the principles of marine navigation have governed the design of dirigible airships. Those who dreamt of great aerial crafts journeying from one inland port of call to another, and voyaging over housetops and forests, were unquestionably inspired by the performances of sailing vessels, and later, of giant steamships. There were difficulties which no engineer seemed able to overcome in placing aerial navigation upon the same sure footing as traveling by sea. The gas bag seemed too much like a huge, unwieldy soap bubble, which might be easily pricked and which could not weather a storm with the same facility as a great liner. The last ten years have witnessed a remarkable change in the attitude of the engineering world toward the dirigible. There is no reason, as experience has taught, why the dirigible cannot be made stout enough to weather any storm. Indeed, we have lately seen that the giant Zeppelins are far safer in the air than they are on the ground simply because of the impossibility of training two hundred men to act in harmony when it becomes necessary to guide the huge gas bag into a shed.

It soon became apparent that if the dirigible was to be speedy and was to have great endurance, it must be made larger than heretofore. The dirigibles of our day are some of them six times the size of the first airships that were considered practical. The larger they grew the safer they became in the air. And the larger they grew the more like the ocean steamship they became in their appointments. A modern Zeppelin or Parseval, with its huge railed-in engines, its board floor, its brass fittings, its comfortable chairs, is astonishingly like a well-equipped trans-Atlantic liner. Modern air travel has driven home the theoretical truth that as you make a dirigible larger it also grows smaller in a sense, a paradox which even engineers have only lately admitted.



The problem of transportation consists in handling the largest load with the smallest amount of machinery possible. It is far cheaper to convey 40,000 tons in one steamer than in two, to haul a huge load by a single 425-ton locomotive than by two 250-ton locomotives. If the dirigible is ever to become a factor in the commercial transportation of cargoes it must be big. The dirigible can be increased in every direction, with a corresponding increase in lift. The aeroplane can be increased in size only in one or two planes, and then at the risk of obtaining surfaces so huge that they cannot be properly supported or easily managed.

The bigger the dirigible airship can be made the greater are its advantages. First of all, there must be considered the increased radius of action with a single charge of fuel; secondly, there is increased speed; thirdly, there is a relative diminution of gas losses; fourthly, there is the possibility of ascending to great heights, and of profiting by wind changes at different levels; fifthly, there is the assurance that rain, snow, sleet, can have no serious effect upon the structure; sixthly, there is obtained a surface so tough and stout that no sheds are required; seventhly, there is greater safety at anchor; and eighthly, there is more comfort to passengers.

First of all we must show how the size of the airship can be increased without weakening the structure or increasing its weight inordinately, and next, how and why the eight different advantages enumerated are attained, and finally, why dirigibles of large size are more safely handled near the ground than small vehicles.

A giant dirigible could be constructed, to my mind, by combining tens, and even hundreds, of dirigibles of the present size, and bundling them into the proper shape. It is obvious that this bundle can weigh no more than the sum of the weights of which it is composed. If this bundle could be propelled by the combined force of the motors of these small dirigibles, it would obviously move much faster through the air than if each small dirigible flew singly. Why? Because the placing of many dirigibles behind one another will decrease the head-on resistance, so that the surfaces behind the bow would meet with no resistance but skin friction. It is true that skin friction is nowadays considered a serious obstacle to high speed, but a bundle of dirigibles will have less skin friction than all the dirigibles flying singly, simply because in a bundle only parts of the surfaces of the outer dirigibles are exposed to the atmosphere.

The scheme could be carried out far more easily than may appear at first blush. The load in fuel, motors, propellers, rudders, and ballast, must be so distributed that each gas bag has principally one kind to carry. The dirigibles on the outer side of the bundle would alone be provided with propellers and rudders (and the rudders would be confined exclusively to the bow and stern). These propellers and rudders would be distributed over about one-third of the outer surface. One large rudder would be excessively heavy if sufficiently strong; therefore, a large number of small rudders must be installed instead.

Copyright, 1911, by Munn & Co.

Sectional view of a titanic airship with elevators to take passengers from the lower deck to the observation passageway on top of the craft.

Within the bundle will be found auxiliary machinery, dynamos, ventilators, living quarters, store rooms, and fuel tanks. Externally, the bundle will appear as a giant torpedo, with no huge car suspended below. Whatever cars there may be will be more in the nature of a continuous saloon, forming practically part of the under surface of the bundle, so as to cut down head-on resistance. Some projections there will be, such as promenade decks, bridges, observatories, wireless antennæ, and the like—all too small, however, to break the general outline. Indeed, the only projections that might cause comment (aside from the lifting horizontal aeroplane rudders) are the hundreds of propellers studding the entire surface, ranged in rows around the entire outer surface in spirals of small pitch, not unlike the rifling that runs within the bore of a modern gun. Such a spiral arrangement avoids interference of many propellers with one another, so that each may work in undisturbed air. Only the bottom surface of the bundle, to which the saloon is attached, is free from propellers.

In principle, these propellers are like those which Zeppelin has so effectively employed. They will be mounted as he mounts his, except that those near the bow and stern are to be swiveled so that they can be swung in any direction to exert a steering effect, and to assist the rudders, especially in landing.

Horizontal rudders of the multi-plane type used by Zeppelin are distributed along the flanks of this huge dirigible. Vertical rudders of the same type are clustered around bow and stern.

Most important of all are the internal arrangements of this mammoth airship. The Zeppelin compartment system of storing gas is developed to the utmost. There will be hundreds of gas cells, many "inside cars" or small gas-tight compartments to accommodate motors, machinery, stores and passengers. Special ventilating apparatus will be required to keep the air free from hydrogen so as to prevent the formation of an explosive mixture. The machinery must be so distributed that its weight will be carried by certain groups of gas cells. The walls of the gas cells are designed to form tunnels so as to provide passageways between the "inside cars." Piping and electric wiring (suitably protected) runs through the whole interior structure.

In more or less close proximity to the outer skin the gas cells are traversed by shafting from the many motors, and by transmission gears to operate the many rudders.

It goes almost without saying that the rigid system will be used in the construction of this aircraft. Theoretically, the entire complicated fabric might be held without buckling by balloonettes kept distended by blowers. In practice, however, it will be difficult indeed to use any but the rigid system. There is this point gained, however, that with this "honeycomb system" rigid construction is less wasteful of weight than in a Zeppelin. The frame does not need to be so strong, as the buoyancy of the gas itself braces the whole structure, for the bracing effect which in a spherical balloon the gas exerts only on the upper part of the envelope, is here extended over the entire structure. Nevertheless a dirigible built along these lines is subject to certain limitations as regards size. The first point which has to be considered is the necessity of keeping the balloon right side up. This forbids us to distribute the weight quite uniformly throughout the whole structure, for of course there must be an excess of weight at the bottom. This requirement introduces an element of weakness in very large dirigibles. We have here a very good illustration of a general principle, namely, that as a structure is increased in size its weight and strength do not increase in the same proportion. For even if we only consider the ropes by which the balancing weight is attached to the envelope, as the size of the airship is increased, these ropes must be made both thicker and longer. Now their strength is proportioned to the thickness, their weight, on the other hand, to the product of their thickness into their length.

Another limiting factor is found in the internal stresses set up during any sudden acceleration or retardation. It has been tacitly assumed that each gas cell is proportioned only to take care of the inertia or momentum of the load which it has itself to carry. As a matter of fact, it must, in addition to this, bear the cumulative strain of the loads of the entire row of cells in front or behind, as the case may be. This difficulty, however, is not as serious as at first sight appears, for the mass of the outer envelope and the inner framing is so large in proportion to the surface, that very abrupt motions of the ship are practically out of the question. A third limiting factor which suggests itself, would seem to lie in the fact that the thrusts of hundreds of propellers would have to be borne entirely by a single prow, which would either be unable to sustain this stress, or else would have to be made stronger and heavier than would correspond to the individual dirigibles of which we have imagined our bundle to be composed. As a matter of fact this objection also is fallacious, and the thrust of the numerous propellers is not really cumulative, for the resistance against rapid flight arises chiefly from skin friction. Hence the thrust of each propeller is taken up mostly just at the point where it is applied—along the flanks. Nevertheless, such limiting factors as these do unquestionably preclude an indefinite increase in

size of the balloon. Yet the dimensions which are permissible are almost incredibly large. Moreover, a great advantage can be gained by neutralizing the crushing effect of any local wind pressure. This can be effected by the simple expedient of providing suitable vents through which the air pressure produced by the wind finds its way instantly into the interior of the structure. In this way the pressure against the prow in rapid flight is taken up quite as much by the rearmost internal gas cells as by the forward ones. The pressure from within is rendered equal to the pressure from outside. (The small and flimsily constructed captive balloons known in Germany as "kite balloons" are built on this plan and have weathered hurricanes that tore them from their cables but were powerless to crush them.)

The vents should be well proportioned and provided with valves, as it might be found best to limit the pressure of the wind, with the result that the strain on the side of the structure would be eliminated in spite of the hundreds of revolving propellers. The thrust of the air resistance in front is neutralized (in the material) by the pull of the suction in the rear. Thus, for instance, we may have a pressure of ten pounds per square foot upon the outside of the prow; the vents might provide a pressure of five pounds per square foot on the inside, leaving five pounds per square foot to be taken up by the material along the sides. But the vents also provide five pounds per square foot on the inside of the stern, and this pressure is not opposed by any counter force from outside, but on the contrary is assisted by a suction. This results in a pull along the sides in the material, which exactly compensates for and eliminates the compression.
